In the middle of the seventeenth century the Jesuit Athanasius Kircher¹⁶ described how a hen, bound by her feet and laid on a pavement until she ceased to struggle, could then be kept motionless by drawing a line in chalk away from her eye and straight in front of her. From that day to this the possibility of inducing a state of trance, however well attested, has been generally regarded with distrust. It was so in the case of John Elliotson, who in 1838 was forced to resign the Chair of Medicine at London University because he practised mesmerism. It was so in the case of Esdaile, though his work was vouched for by an officially appointed committee of investigation. The sincerity of Sampimon and Woodruff is unquestioned. Their experiences are at variance with the everyday practice of anaesthesia and the usual reaction of the human organism to pain. The time may be due for a thorough review of the subject of hypnosis and suggestibility in relation to surgery. Sampimon and Woodruff press for such an investigation, for much good might come of it. They suggest that the work might best be undertaken by a surgeon, or better still, we believe, an anaesthetist, collaborating with a psychiatrist.

WATTS EDEN TRAVELLING FELLOWSHIPS

Dr Thomas Watts Eden, who died on Sept 22, 1946, set aside under the terms of his will two sums each of £10,000 free of duty, to found travelling fellowships. These two fellowships will be created after the death of his widow. One is to encourage the study of obstetrics and gynaecology, the other the study of infancy and early childhood in health and disease. For thirty years or more Dr Watts Eden was one of the foremost obstetricians and gynaecologists in London hospital and consulting practice. He distrusted that narrow specialism which he called "the key hole view" of medicine and often stressed the need for study of the healthy infant and child, and particularly in relation to the results of antenatal and postnatal care. The conditions under which these two new fellowships are to be founded reflect his views. In due course the funds set aside by his trustees will be transferred to the Royal College of Physicians and to the Royal College of Obstetricians and Gynaecologists. The Presidents and senior officers of the Colleges, with others, are to be the judges making the awards. Candidates will be men or women graduates whether members of the College concerned or not, of at least two years' standing of any approved university in the British Empire and Commonwealth. Each fellowship will be for a period not exceeding three years. The awards will be made according to the academic progress of a candidate before graduating and in the light also of his or her attainments during the postgraduate period. Ten years after the first award the conditions may be varied.

On Monday of last week Lord Moran was once again elected President of the Royal College of Physicians.

MEDICAL HISTORY IN POSTAGE STAMPS

The medical profession is much given to the cultivation of hobbies. It is, therefore, rather surprising that the medical associations of philately should have received such little attention or have been pursued in secret. The exhibition illustrative of 'Medical History in Postage Stamps,' held on April 2 at the Historical Section of the Royal Society of Medicine, under the presidency of Sir Arthur MacNalty, appears to have been the first of its kind in this country. This exhibition was arranged by Mr N M Matheson and Mr W J Bishop and was accompanied by a demonstration on the epidiascope and a running commentary.

Until comparatively recent times stamps of medical interest were few, but within the last twenty years designs illustrative of almost every aspect of medicine have multiplied, and their number and range are sufficient to give scope to the most ardent collector. Medical stamps may be divided into two broad classes: (a) those bearing portraits of medical men, and (b) those depicting medical scenes such as hospitals, nursing medical congresses etc. There are many special health, Red Cross, child welfare and tuberculosis stamps, on some the only distinguishing feature is the Red Cross or the tuberculosis symbol.

The stamps which will probably most interest the medical man are those bearing portraits of medical and scientific worthies. The first medical man to be depicted on a postage stamp appears to have been F Espejo (1746-99)—Ecuador, 1899 issue. In 1923 France began the well-known series commemorating Pasteur but the first medical man of eminence to be so honoured was Boerhaave (Netherlands 1928). After his date the number of portrait stamps increased rapidly, and

they may be divided into those of practising medical men, those who qualified but abandoned medicine, those who studied but never qualified, and workers in ancillary fields. Among regular practitioners we find Vesalius, Paré, Haller, Semmelweis, Camper, Purkinje, Ramon y Cajal, and Reed. No stamp is known commemorating the Father of Medicine, but Imhotep, Apollo, Aesculapius, and Hygeia have been honoured. Some fortunate individuals appear on the stamps of more than one country. Van Swieten has been so honoured by the Netherlands and Austria, Koch by Germany and Danzig while Pierre and Marie Curie appear on several stamps. Harvey, Sydenham, Hunter, or Jenner will not be found on any stamp. Indeed it was not until Sir Wilfred Grenfell was depicted on a Newfoundland stamp of 1941 that any British medical man had been commemorated in this way. Some countries have issued stamps portraying whole schools of medicine—e.g., the nine worthies of the Vienna school issued by Austria in 1937. Vesalius, Dodoens, and Van Helmont appear in a recent series from Belgium. Among 'truants' from medicine we have such diverse figures as Sun Yat-sen, Clemenceau, Chekhov (third from left in bottom row), and Schiller and among those who studied but never qualified we find William Henry Harrison, ninth President of the United States—a pupil of Benjamin Rush. Ancillary sciences are represented by such names as Roentgen, Berzelius, Ampere, Volta, Galvani, and Ling. Florence Nightingale appears on French and Belgian stamps and Jean Henri Dunant, the founder of the Red Cross, on Belgian and Swiss stamps, and the German stamp shown on the left of the bottom row records ten years' child welfare work.

As Matheson and Bishop showed, the "documentation" of a collection of medical stamps would provide a searching exercise for the student of medical history. The value of such a collection for purposes of teaching and illustration is obvious, and perhaps this comparatively new branch of collecting will attract many doctors who have not previously come under the spell of either medical history or philately.

We are indebted to Mr W J Bishop for permission to reproduce the stamps illustrated in this article

POLISH FACULTY OF MEDICINE IN EDINBURGH

The first medical school in the United States was started at Philadelphia in 1765 by William Shippen and John Morgan, graduates of the Medical Faculty of Edinburgh. At the beginning of the 19th century Andrew Sniadecki made use of his observations when a medical student at Edinburgh under Duncan, Monro *tertius* and Gregory to found at Vilna the first modern medical department in a Polish university. But although a Danish student two hundred years ago remarked that at Edinburgh one could see wandering together students from places as far apart as America, France, Portugal, and Russia, the existence in the Scottish capital of a separate foreign school of medicine is something unique not only in this city but anywhere.

The Polish Faculty of Medicine in Edinburgh, now to be disbanded, was formed in 1941 as a result of an agreement signed by Sir Thomas Holland, then Vice Chancellor and Principal of Edinburgh University, and Dr Stanislaw Kot, Minister of the Interior in the exiled Polish Government in London. The Polish Army which escaped from France in 1940 was largely concentrated in Scotland, and arrangements were made for Polish medical officers to obtain instruction in British military medical methods by attending the military hospital at Edinburgh, and in certain cases working in the medical departments of the university. To overcome the language difficulty Lieut-Col Crew, commander of the military hospital and in peacetime professor of genetics at Edinburgh, conceived the idea of forming a postgraduate course for Poles, conducted by Polish teachers. This idea broadened into the establishment of a complete Polish school of medicine to train Poles in this country as doctors. Accordingly a Polish Faculty of Medicine was formally inaugurated at an impressive ceremony in the M Ewan Hall on March 22, 1941.

For five years Poles came to Edinburgh from the battlefields of Europe—from Norway to Monte Cassino, from Falaise to Kapelle—from the underground army inside occupied Poland, and from Russia to study medicine in an institution which was their own though their country was overrun. They used the old anatomy department building in Bristo Place and practicals were also held in the Royal (Dick) Veterinary College, clinical studies were carried out in the Royal Infirmary, the Simpson Maternity, and city fever hospitals, and the specially established Paderewski Hospital. The Dean of the Faculty was Dr Antoni Jurasz, later succeeded by Dr Tadeusz Rogalski, and in addition to the Polish lecturers the following professors of Edinburgh University took part in the teaching of the students: Sydney Smith, T J Mackie, Stanley Davidson, A M Drennan, and R W Johnstone. The staff consisted altogether of 54 persons—including 9 professors, 9 senior lecturers, 21 senior assistants and 8 junior assistants.

The number of students at the school in the last year of its existence was 241, about one third of them being women. The Polish students each year elected representatives to the Edinburgh University Students Representative Council, and one was made assistant secretary of this body. The Poles took part in various student activities and had their own students association and a hostel, although most stayed in "digs." Scottish students and members of the Edinburgh University teaching staff proposed at one time that the Polish school should continue in peace and an equivalent body be organized in Poland although the Goodenough Committee had reported that the clinical facilities at Edinburgh were insufficient to support the two British medical schools there. There is no

doubt, however that the Polish Faculty of Medicine in Edinburgh University represents a successful experiment in international medical co operation which might well be followed in other spheres

MENTAL HEALTH AND THE OFFENDER

Dr J R Rees's Clarke Hall Lecture

The seventh Clarke Hall Lecture on "Mental Health and the Offender" was delivered by Dr J R Rees at Lincoln's Inn on March 26, with Mr Justice Birkett presiding. Dr Rees said that in the past the psychiatrist had been regarded as concerned in the main with those grosser mental disorders the psychoses, which, however, were but a small part of the whole field of psychiatric interest. As an example, although it was admittedly from a somewhat selected group, out of 225,000 men and women in the Army during the recent war who were referred to psychiatric out-patient clinics, only 3.5% were cases of psychosis, 27% of the total were cases of mental dullness or defect, and 57% were cases of neurosis or of psychopathic personality with lifelong emotional and social instability. Crime was the outward manifestation of some disorder in personality and character, however this might have been caused, and all antisocial conduct, whether it was noticed merely in the nursery or came eventually to the courts, was evidence of some psychological failure in the conduct of life. There was no effect without cause, and it was vitally important that an attempt at diagnosis should be made before treatment was undertaken. Whether the condition was regarded as a disease or as a character disorder, neither implied something for which the individual must be assumed not to be responsible. There was a certain individual responsibility for common physical illnesses, such as the cold and a multitude of other minor conditions, and the responsibility for emotional disorders and upsets was exactly parallel.

Psychiatrists in Court

In Army courts martial the excellent principle had been established, Dr Rees continued, that psychiatrists were to be allowed to be called for the defence. Their report were always to be given to the president of the court before the consideration of sentence. He wished that psychiatrists, and indeed all medical men, could be regarded in the light of experts giving their advice to the court, and not, as too often happened, being brought in by one side or the other merely to support the efforts of counsel.

Far too frequently when a medical report was demanded it had to be provided by someone who was not very skilled in the psychiatric approach. It was essential that at every remand home and in every prison there should be psychiatrists and psychologists with the necessary special training and experience to investigate, report on, and interpret the material referred to them. Up to the present the average doctor had had but little training in this field, though many senior men had acquired great wisdom through experience. Whether tackling the medical or the sociological problems concerned with mental health, a team composed of those people who had special interest in, and knowledge of, the behaviour of human beings would always be desirable. The sociologist, the psychiatrist, the penologist, and the psychologist had equal status in the team. He thought they were beginning to realize in medicine that the persistence of the old, unjustified sense of superiority of the doctor over his technically trained colleagues in allied fields did nothing but hinder progress.

What was needed, in his view, was the ability to recognize the kind of human beings who had committed crime, the attitude to the offender should be to hate the thing he had done but not to hate him, just as doctors should think of the man or woman who was ill, even if this meant thinking a little less of the illness from which he or she suffered. There was an aversion among some in the legal profession that their colleagues in medicine were sentimentalists while they themselves were realists. Very often the reverse was the truth. The doctor being used to disease, suffering, and the less pleasant aspects of life and death should be able to see through the circumstances surrounding some particular crime to the essential problem, and once the facts were established, which normally

had nothing to do with him, he should be realistic in his assessment of the quality and make-up of the individual and what might best be done with him with a view to making him a healthy citizen

REVISED PENSIONS

There are still about 28 000 men of the 1914 world war receiving pensions for the loss of one or more limbs. For the recent war the number is something over 10 000. These pensions have previously been calculated on a schedule of assessment for certain specified injuries laid down in the Royal Warrant. During the discussions at the Committee Stage of the National Insurance (Industrial Injuries) Act, in November, 1945, it was suggested that a committee might be set up jointly by the Minister of National Insurance and the Minister of Pensions to review the existing schedule of assessments and to consider whether any changes should be made as a preliminary to its common use in both Service and industrial cases. The committee which was subsequently set up had six medical members¹ and was presided over by His Honour Judge E. Hancock.

The degree of disablement in any case is in most instances settled by a medical board. There are a group of cases, however, which lend themselves to more general assessment—namely, those cases involving the loss of a limb or part of a limb. Provided there is an exact description of the injury the compensation or pension can be fixed by reference to a schedule. The committee has considered these injuries and certain minor injuries ranging from the loss of a toe or finger downwards. In most instances the assessment which was previously in force remains unaltered, but the committee has recommended a few changes. In future the rates for the loss of a hand or arm will be the same irrespective of whether it is the right or left hand. Thus, in future, the loss of four fingers of one hand will be assessed at 50%, as against 40% for the right hand and 30% for the left hand, which is the present assessment. The assessment for amputation of the hip joint will be raised to 90% and there are other minor changes. Any increases of pensions resulting from adoption of the new schedule will have effect from the first pension pay day in April. It is estimated that about 7,000 pensioners will benefit from the new arrangements and the increased cost to the Exchequer will be slightly over £100,000 a year. The Minister of Pensions has accepted the committee's recommendations, and so far as industrial cases are concerned the committee's findings have been accepted in principle by the Minister of National Insurance and will be used as a basis for the regulations to be made under the National Insurance (Industrial Injuries) Act.

GUY'S HOSPITAL DENTAL SCHOOL

The first annual clinical meeting since 1939 was held at Guy's Hospital Dental School on March 30 when a full programme of demonstrations of modern dental work was carried through by members of the staff. Special interest attached to demonstrations of apicectomy under nitrous oxide anaesthesia, the operative treatment of prognathism, the facilitation of extractions using local analgesia and in the children's department, orthodontic cases under treatment. It was stated that the school's growing so rapidly and the number of patients undergoing treatment is so large—more than 13 000 new patients were treated during 1946—that plans are in preparation for rebuilding the department as soon as conditions allow. There are 100 students in training. Hitherto admission has been restricted to male students but from September next women students will be accepted. In 1946 a professor of dental medicine was appointed by the University of London, he is to be assisted by a team of assistants and is to carry out research into various aspects of dental disease. A proportion of the cost of this research is being borne by the Nuffield Foundation. Another feature of Guy's is a department of preventive dentistry, which aims to bring home to the public a knowledge of the means of prevention of diseases of teeth and gums. The school is the first in the country to undertake the training of women to assist general dental practitioners in their chairside work.

MENTAL AFTER-CARE

Dr Henry Yellowlees, the chairman of council, presiding at the annual meeting of the Mental After Care Association said that all the activities of the Association had been kept up to standard. They were of a practical nature, dealing with adults recovering from nervous or mental illness and with the prevention of such illness by early care. The Association had never been concerned to organize or arrange lectures on mental illness but it had co-operated with other bodies and had given financial help whenever possible, as well as advice in individual cases when referred by clinics. It was desired to develop one of the Association's homes as a special rehabilitation centre, also to expand the work and become a national association with branches instead of being a London association. Dr W. Gordon Masefield paid a tribute to the work of the Association. As a medical superintendent he had found that one of the most difficult problems to solve concerned the patient who was ready to leave the mental hospital and who needed chiefly to have his self-confidence restored, and here in the convalescent stage of mental illness a short period in a home such as the Association provided was of inestimable value.

Preparations and Appliances

STERNAL TROCAR AND CANNULA

Mr HAMILTON BAILEY, London, W 1, writes. With this latest model of a sternal trocar and cannula it is impossible to enter the mediastinum. The instrument can be inserted into the bone marrow under local anaesthesia without any special experience. It is my belief that this method of administering parenteral fluids has a large field of usefulness, for I am constantly encountering cases where either all the available

veins have been utilized, or, for other reasons, cannulization of a vein is hazardous. Cannulization of the sternal bone marrow can be accomplished swiftly under any conditions, including an indifferent light.

After a number of experiments and minor alterations, we (I include Mr P. Regen, of Messrs Willen Bros 44 New Cavendish Street, W 1) have now perfected the instrument and have made it foolproof.

The Secretary of State for Scotland has approved increases of salary ranging from £30 to £75 per annum for matrons and deputy matrons of mental hospitals recommended by the Wheatley Committee. In the case of chief male nurses and deputy chief male nurses the increase is one of 20s per week. The increases take effect from July 1 1946, the date on which increases for the other grades of mental nurses came into effect. Registered general nurses who train in mental hospitals will now get £115 in their first year and £130 in their second year of training, instead of £90 and £100 together with free board and lodging. Men and women with war service who are or who become qualified mental nurses may now get credit for all or part of that service.

Reports of Societies

LOCAL PENICILLIN IN THE MOUTH

At a meeting of the Section of Odontology of the Royal Society of Medicine on March 24 with Prof H STOBIE in the chair, a discussion took place on penicillin used locally in the mouth.

Dr ALEXANDER MACGREGOR said that the action of penicillin *in vivo* in the mouth at all events, appeared to be greatest within the first quarter of an hour. The speed of diffusion of penicillin was an advantage in the odontological field, because the drug was able to reach areas like gum pockets quickly, but at the same time it had the disadvantage that the penicillin was rapidly lost. He had employed penicillin pastilles in the hope of getting a slower action. Other methods of administration were penicillin powder, which was of value for insulating cavities, cream, as to the advantages of which he was uncertain, and the most recent method of using cones with a fatty base. It was essential to have a base which would not interfere with the healing of a socket, and whether the cones would prove successful over a long series he could not as yet say.

One of the main indications for local penicillin in the mouth was Vincent's disease. In the acute form of this condition penicillin was better than any other treatment, in the chronic form it was unavailing. There was usually some focus of infection such as an impacted wisdom tooth, which must be eliminated or recurrence was likely to take place. The acute stage was controlled within four or five days, and it was striking to see the improvement in the patient's condition coincide with the disappearance first of the spirochaetes and afterwards of the fusiform organisms. The results of local penicillin in ulcers of the mouth had been very mixed. Some of the so-called dyspeptic ulcers in the mouth appeared to be associated with streptococci and pneumococci and others with mixed oral types of organisms. Some of the cases cleared up quite well and did not recur but others did not improve. In extractions operations on cysts and gingivectomies penicillin was of value in obtaining a clean field in which to work. In carrying out gingivectomy he did not pack, instead of packing, he employed massage as soon as possible. He found that with penicillin pastilles the amount of pain subsequently appeared to be very much reduced. In chronic gingivitis penicillin was of little value but in certain cases it did bring about a temporary relief of the condition, which gave time for other treatment to be started.

Concerning the pastilles themselves Dr MacGregor said that he had used a pastille with a gelatin base. The disadvantage was its high water content, penicillin lost its stability rapidly in contact with water. The pastilles were not very stable, and unless used quickly the penicillin content dropped and the administration was rendered useless. But there was no doubt that such pastilles when fresh were very much better than the commercial ones with a hard base. He considered that the modern hard-base pastilles were not completely safe. With the gelatin base the stomatitis which made its appearance with other forms of lozenges was not encountered. If odontologists had gelatin pastilles made up in their own dispensaries with fresh penicillin, he thought they would be surprised at the results.

Desiring to learn what kind of spread was to be expected with penicillin pastilles in the mouth, he had carried out an experiment in which the penicillin was replaced by methylene blue, and taking 50 subjects he worked out a system of marks for the extent and degree of staining. The proportions for the different areas were

	Anterior Pillar of Fauces	Uvula	Tonsils or Tonsillar Fossa	Pharynx
After 5 minutes	59	47	45	11
15	88	82	73	24

The majority of the cases showed no staining of the pharynx at all.

Finally he pointed out that local penicillin was an adjunct to oral surgery, not a substitute for it, that bacteriological

control was essential, otherwise various organisms might come to the fore and give rise to penicillinase which would abort the effect of the penicillin, and that if penicillin was given at all, it should be given in sufficient dosage straight away. Even though organisms were eliminated it did not mean that they would not come back again. It had been noticed that the elimination of streptococci from the throats of carriers was quite effective so long as the penicillin was being given, but that the organisms returned when the treatment was stopped.

In reply to questions by Prof H F HUMPHREYS and others Mr D A LONG who was associated with this research on the bacteriological side, said that directly coliform organisms made their appearance the local value of penicillin ceased. The appearance of the coliform organisms did not seem to bear any relation to the form of treatment. It might have been thought that if coliform organisms were forthcoming on the second or third day or later with local penicillin they would be seen correspondingly earlier with systemic penicillin, but that was not so. He had carried out some investigations on patients having penicillin systemically, from 100 000 up to one million units a day, and it was not until half a million units was reached, or, more strikingly, one million units was approached, that the organisms tended to disappear from the mouth. In cases in which a really severe infection had spread to the lining of the mouth the dosage should be between half a million and one million to produce the maximum effect. For the treatment of such cases systemic penicillin was vastly superior, largely because of its action over twenty-four hours, the action of local penicillin being limited to the patient's waking hours.

TREATMENT OF TOXIC GOITRE

A meeting of the Section of Endocrinology of the Royal Society of Medicine was held on March 26, Mr L R BROSTER presiding, for discussion on the treatment of toxic goitre.

The Argument for Surgery

Mr J E PIERCY said that primary toxic goitre offered a difficulty in diagnosis. Thiouracil was invaluable in breaking down the degree of thyrotoxicosis to safety level, and in the average case it eliminated the necessity for stage operation. But thiouracil increased the technical difficulties of operation by reason of the increased vascularity and added 20 or 25 minutes to operation time. It was the secondary nodular type of gland which was difficult to recognize. Here there were few signs and symptoms, the patient possibly complaining of fatigue and palpitation on exercise. This type of case appeared to go on unsatisfactorily below toxicity and culminated in cardiac damage. The importance of these slow going minimum degree toxic cases should be appreciated. Out of 1,000 nodular goitres 220 had developed auricular fibrillation by the time they were admitted for operation. The procedure called for close co-operation between physician and surgeon and a study of the individual case, there could be no uniformity. Cases needing most consideration were those with mental derangement associated with thyrotoxicosis.

Even in the case of the severely toxic patient and the patient with complications he thought that a return to normal or near-normal could be expected. Thyrotoxicosis commonly occurred in the highly strung sensitive type of patient and although the thyroid balance might be regained by operation the constitutional make-up was unaltered. It was generally recognized that the nursing profession was a particularly exacting and arduous one but of 65 nurses operated on in his series all had returned to full duty—an indication of the effectiveness of the operation. In surgery not only was the thyrotoxicosis dealt with rapidly but the goitre also. Auricular fibrillation or the risk of it in the future was practically removed. A bad scar was unusual and such scar as there was should not give rise to pressure. In comparing the results of operation with those of thiouracil treatment the long strain on the patient during treatment by the preparation must be borne in mind as well as the ever present fear of complications. His argument for surgery was based on the conviction that it offered a more rapid cure than thiouracil and with no greater mortality.

Thiouracil Treatment

Dr W R TROTTER discussed the treatment of toxic goitre by prolonged administration of thiouracil. If this drug was given to a patient with toxic goitre it would be possible to reduce or abolish the manifestations of thyrotoxicosis, but as there was no evidence that thiouracil had any permanent effect on the thyroid it was to be expected that if the drug was discontinued the symptoms would recur immediately, unless it should happen that in the meantime a natural remission had taken place. Reduction in the size of the goitre or amelioration of the exophthalmos was not to be expected. The practical utility of the drug would depend, first of all, on its ability to control the symptoms of thyrotoxicosis; secondly, on the frequency with which natural remission of the disease occurred; and, thirdly, on the extent of non-toxicity. If thiouracil was to supplement surgery as the standard treatment of toxic goitre it must be shown that it could control thyrotoxicosis as effectively as operation, and that it was no more dangerous. Most patients would prefer to swallow pills for a limited period rather than undergo an operation, but they would prefer an operation to the necessity for remaining under close medical supervision for the rest of their lives.

The control of thyrotoxicosis by thiouracil was achieved in practice, and all were familiar with the short results. Cases which were resistant and responded slowly were those which had had long periods of iodine therapy previously. The degree of control obtained was much the same as by thyroidectomy. As for the length of time during which the drug had to be administered before the patient reached natural remission, out of 29 cases, 7, owing to the return of thyrotoxicosis, had had to be put back on thiouracil after the treatment had been suspended. These must be considered as true recurrences of the disease, since the symptoms did not reappear immediately after the drug was stopped. The fact must be faced that at least 25% of cases were likely to relapse and require a further course of treatment after the first had been completed. Experience showed that a natural remission might be expected to set in within a year or two of the patient's first coming for treatment and it was not yet known how curable these remissions might be. In some patients at least there was reasonable prospect of permanent remission. What was needed was some means of distinguishing the case in which remission would be obtained from the case which would show a persistent tendency to recur.

Toxicity of Thiouracil

Concerning the toxicity of the drug, the complications most common were the skin symptoms, drug fever, and leucopenia. For the most part these conditions were not much more than a nuisance and did not necessitate stopping the treatment. The proportion of cases in which treatment by thiouracil had to be abandoned on account of complications was not more than 18%. Agranulocytosis was a different matter. Its high death rate and unexpected onset made it an alarming condition. There were at present no means of preventing its onset, but a great deal could be done by alertness and promptitude in treatment to prevent it from being fatal.

In comparing this new agent with the well-established method of subtotal thyroidectomy two factors must be taken into account: the type of surgery and the type of case. Subtotal thyroidectomy could be an extremely difficult operation. Its safety depended not only on the skill but on the experience of the surgeon. By the time a surgeon had done several hundred such operations his mortality rate might be less than 1%, but many general surgeons did not have the opportunity of acquiring this degree of experience and their mortality was correspondingly higher. It followed that while thyroidectomy in the hands of an expert was as safe as treatment by thiouracil, thyroidectomy by surgeons without special experience was less safe. It seemed a fair conclusion that where a specialist surgeon was not available a physician might be well advised to treat all these cases with thiouracil in the expectation that by doing so he would save lives. When expert surgery was available then more discrimination between the two procedures might be exercised.

Dr A M MUSSEY mentioned a series of 75 cases treated with thiouracil in three years and gave an account of his routine

method. He had not found the exophthalmos much affected. Out of 7 cases with thyrotoxicosis associated with auricular fibrillation, rhythm had returned in 4 and in 3 there had been no change. He had treated pregnant women who had given birth to normal babies. Contraindications were a preference expressed by the patient for surgery for cosmetic or other reasons, exertion of pressure by the gland, serious complications arising in the course of treatment, failure to control the disease without pushing the drug to dangerous limits, and lack of co-operation by the patient. Surgery had achieved its present status not without trials and errors, and not without casualties. By patience and perseverance an effective medical alternative had been evolved. The last word on the subject had not been spoken, and inquiry into new ways of dealing with the problem would continue.

The discussion was continued by Dr LINNELL who was surprised at the suggestion that only a minority of patients showed the nodular toxic type, in his experience the large majority were of that type. Every nodular goitre, whether toxic or not, should be removed. Mr VAUGHAN HUDSON said that the use of thiouracil must be investigated under very well controlled conditions. Too often the results of the very specialist surgeon or specialist physician had been taken but it was important to bear in mind the results so far as they could be ascertained, of random surgeons and physicians. Major ROBERTSON spoke of favourable results with thiouracil. He had been fortunate in the absence of complications in spite of the fact that the initial dose he gave was higher than usual. Dr CROOK spoke of the value of propyl thiouracil—a drug, he claimed as safe to use as thyroid in myxoedema.

DISEASE IN OLD AGE

A meeting of the Medical Society of the L.C.C. Service was held on March 5 at St. John's Hospital, Battersea. The discussion was opened by Dr TREVOR H. HOWELL.

Dr Howell said that in 1900 there were 2½ million persons of pensionable age in the country. Now there were over 6 millions and the number was still growing. Little was known about disease in old age. We had advanced no further than Hippocrates who wrote "In old people occur dyspnoea, catarrhs accompanied by coughs, dysuria, pains in the joints, nephritis, vertigo, apoplexy, cachexia, pruritus of the whole body, insomnia, desfluxions of the bowels, the eyes and the nose dimness of sight, cataract, and dullness of hearing." The records of the Royal Hospital, Chelsea showed the following figures for causes of admission to the infirmary between 1918 and 1943:

Bronchitis	14%	Influenza	8%
Old age, senility	12%	Arteriosclerosis	7%
Cardiac disease	10%	Digestive disorders	7%
Minor surgery, eye, ENT	8%	CNS diseases	6%
Rheumatic disease 6%			

The diseases causing death in the aged were quite different in their order of frequency. They had changed somewhat since the use of sulphonamides became general. Pneumonia, formerly second on the list, now lay seventh. Heart failure was probably more common than before since fewer patients died with acute infections, but more passed on to 'secondary' heart failure after the disease had subsided. The Registrar-General's figures for the causes of death in approximately 250,000 persons over 65 in 1942 were roughly as follows:

Heart disease	30%	Bronchitis	8%
Cerebral vascular disease	14%	Old age	7%
Cancer	12%	Arteriosclerosis	5%
Pneumonia 3%			

His own experience at Chelsea during the war led Dr Howell to realize that deaths from pneumonia would be fewer if sulphonamides were given as early as possible without waiting for clinical signs of consolidation. In a bronchitic old man pyrexia over 99° F (37.2° C) was the danger signal, not signs in the chest. Another advance was the use of injections of adrenaline for bronchial spasm. Such measures not only improved the prognosis of pneumonia but also diminished the occurrence of subsequent cardiac failure.

Dr Howell then drew up a list of conditions common in old age where the prognosis depended on the skill and interest of the medical attendant. Such conditions as bronchitis and pneumonia had already been mentioned, hemiplegia from cerebral thrombosis, chronic arthritis of all types, and normal old age could be greatly influenced by the doctor. Genito-urinary disease and cancer occupied a half-way house, for cure might often be obtained if the condition were discovered early enough. Senile dementia, the results of arterial thickening, and the digestive disorders of old age, on the other hand, were resistant to treatment. The essential motto was, "Spot the cases early and treat them quickly." Dr Howell suggested that the aged and chronic sick needed the best doctors and the most skilful attention. In certain municipal hospitals in Essex and Middlesex this principle had been adopted. Statistics showed that out of every 100 old folk entering those hospitals, 40 died, 40 recovered and returned home, while 20 remained as "chronic sick."

Mr J R M WHIGHAM pointed out that in old people appendicitis often presented with atypical signs and that frequently it was only when the abdomen became distended and general peritonitis supervened that the diagnosis became clear. He suggested that diarrhoea in chronic cases, which was often due to carcinoma of the rectum, should be renamed constipation with overflow.

Mr IAIN MATHESON gave some figures for the mortality following operation in patients over 70. His gross mortality in 169 major operations was 36.5%. He pointed out that a major operation in an old person, even if successful, frequently shortened the expectation of life. With regard to old people in general, he suggested that confinement to bed was often the last straw, and said that a lot of incontinence in old people confined to bed was due to a mixture of laziness and slight mental deterioration.

Dr J H SIMMONS asked what was meant by senility, and suggested that a large number of cases so diagnosed proved to be due to avitaminosis, especially in old people living alone. Dr B GOTTLIEB said that he was getting good results in the treatment of pneumonia in chronic bronchitics with aerosol penicillin.

OPHTHALMOLOGICAL SOCIETY ANNUAL CONGRESS AT GLASGOW

The 67th Annual Congress of the Ophthalmological Society of the United Kingdom was held at Glasgow University on March 27, 28, and 29. Prof A J BALLANTYNE, the president, delivered an address of welcome to over a hundred members and to the visitors from abroad, in particular Dr P Merigot de Treigny (Paris), Dr E Godfredsen (Denmark), Dr J Van Caneyt (Belgium), Prof W H Melanowski, Madame Schiss Wertheimer, and Madame Dallon.

De Senectute

The process of ageing as illustrated by familiar disorders met with in ophthalmic practice was the theme of Prof Ballantyne's presidential address. He began by saying that 'it all depends what you mean' by old age. If what was meant was gradual recession of bodily powers then old age was inevitable but if it was intended to imply that certain particular disabilities were necessarily attendant upon advancing years the story was somewhat different and the outlook more hopeful. Many of the disabilities which in a former generation made people old at fifty had been cleared away, some of them as the result of a change in social habits. If old age meant a stooping gait, some increase of girth, greying hair, a little breathlessness on exertion, a less acute hearing, a less instant memory, then the ageing man, after the first shock of realizing that what he had said about his friends applied to himself, accepted the situation without any very sharp regret. After all, the whole of life was a process of growing old. Histologists and embryologists declared that ageing was a life-long process. Some would have it that the fundamental factor in the ageing process was dehydration, and this actually began before birth. These changes, Prof Ballantyne pointed out,

did not keep pace uniformly throughout the body, each of the organism pursued its own career according to its individual time-table, and the chemical and physical factors concerned were so numerous and complex that it was to be expected that some minor circumstance might often upset the balance and precipitate premature degeneration. In the eye the principal changes regarded as senile were cataract and presbyopia. But opacities of the lens occurred at all ages and senescence of the lens was not necessarily accompanied by opacity. Even when opacities began to appear, visual acuity might remain undisturbed. In the lens as in other tissues there were certain results of ageing which began in early life and over which the individual had no control and to these must be added the further results due to accident. Prof Ballantyne suggested that the doctor-patient relationship was of special value in the instance of the ophthalmologist and his ageing patient. To many people cataract had a sinister significance and patients were grateful for the assurance that useful vision might be retained, and that even opacities of the lens might be regarded in the same category as greying hair and other harmless signs of growing old. He considered it not too much to predict that cataract might be prevented or so retarded that the lens would outlive the individual. Prof Ballantyne concluded with some remarks on the social aspects of old age, on the modern science of geriatrics, and on the "age guidance" specialist. Ophthalmologists, he said, could help their patients to accept with courage a different pace of life. The secret of happiness in old age was congenial occupation, the preservation of a sense of progress, and a sense of one's own significance to family and friends. "The best contribution the older people can make is to cultivate the society and companionship of the young, and, avoiding patronage and superiority, to impart their experience, to offer kindly criticism and, most important of all, to recognize their own limitations and to know when they are in the way."

Rhinology in Relation to Ophthalmology

This discussion was opened by Dr J MARSHALL, who dealt with the ophthalmological aspects of the subject. Mr G H HOWELLS, describing the part played by the ear, nose and throat surgeon, and Dr R MCWHIRTER who showed some admirable radiographs. The opening speakers had agreed to discuss nasal sinusitis as a possible cause of retrobulbar neuritis and intra-ocular inflammation. The trend of the discussion was in favour of referring cases of orbital inflammation to the rhinologist. With his co-operation, sulphonal and penicillin therapy should be undertaken. It was preferred to drain into the nose an abscess arising in an infected sinus. If drainage through the orbit was indicated, then it was best to do this in a plane between the orbital periosteum and bone and not to open the orbital fascia. The value of radiotherapy in the treatment of malignant neoplasms originating in the accessory nasal sinuses and invading the orbit was stressed and this treatment was preferred to surgical removal, particularly in the case of malignant neoplasms of the antrum.

For the exploration and removal of neoplasms deep in the orbit the relative merits of the transfrontal approach and the lateral orbital access by means of Kronlein's operation were briefly discussed. The former approach was indicated when the neoplasm had extended beyond the confines of the orbital cavity, the latter when it was certain that the neoplasm was benign. Opinion was more in favour of dacryocystorhinostomy for naso-lacrimal duct obstruction than of West's intranasal operation. Orbital and ocular injuries as a result of nasal sinus operations were mentioned—for example, penetration of the eye, orbital cellulitis, total ophthalmoplegia, and damage of the optic nerve.

Many other papers of interest were keenly discussed and clinical meeting was arranged at the Glasgow Eye Infirmary.

The annual dinner of the Society was held in the hall of the Royal Faculty of Physicians and Surgeons. Sir Davidson proposed the toast of the Society and the reply was given by Dr S Spence Meighan. He proposed the toast of the guests and Dr P Merigot de Treigny replied. Sir Duke Elder's speech about the President was an admirable survey of Prof Ballantyne's qualities as a man and as an ophthalmologist of international repute.

To combat DEPRESSION characterized by 'chronic fatigue'

Depressed patients 'suffering from psychomotor inhibition complain of feeling tired, of not being able to get started on their daily tasks, and of an abnormal inclination to procrastinate. They make up their minds that they are going to do a certain thing but they never seem to get to it. Everything seems too big for them.'*

'Benzedrine' Tablets are particularly valuable in the presence of 'chronic fatigue'. They will, in most cases, help to overcome the depression and thus enable the patient to make a sincere and constructive effort to surmount his difficulties.

for BASAL INTRAVENOUS or TOTAL ANAESTHESIA

SOLUBLE THIOPENTONE
BOOTS is an intravenous anaesthetic of proved value. As a basal anaesthetic prior to general anaesthesia it has been used extensively and has given uniformly good results over a considerable period under widely varying conditions and dosage.

Soluble Thiopentone has been used successfully and is recommended as a total anaesthetic for short minor operations, and also for long operations which do not demand considerable muscular relaxation.

SOLUBLE THIOPENTONE is a mixture of 100 parts by weight of the mono-sodium derivative of 5 ethyl-5 (1-methylbutyl) thiobarbituric acid and 6 parts by weight of anhydrous sodium carbonate as laid down in the B.P. Addendum VII. Available in Boxes of 6 and 25 ampoules of 0.5 gm and 1.0 gm.

Ribena therapy in skin conditions

That vitamin C has some beneficial effect on the health of the skin appears certain from the good results obtained in various skin disorders. Cases of acne rosacea, for example, have been reported to clear up following a course of 'Ribena' Blackcurrant Syrup. In allergic skin manifestations a dietary of green salad, supplemented with 'Ribena,' often proves effective. Clinical tests have indicated that Ribena has been of some value even in psoriasis, perhaps because of its content of vitamin P.

Ribena Blackcurrant Syrup has a high degree of acceptability and is well tolerated even in cases where the condition is complicated by digestive disorder. The vitamin C content of Ribena is standardised at 20 mg per fluid ounce, with which are associated other factors of the natural product whose precise functions have not yet been clearly established.

In the treatment of the Menopausal Syndrome

The use of oestrogens for the control of menopausal symptoms is an established practice. The following B.D.H. oestrogens are available —

OESTROFORM — the most generally satisfactory preparation for menopausal patients. Treatment is by means of injection, therefore it is completely under the control of the physician.

STILBŒSTROL B.D.H. — the most frequently present of the synthetic oestrogens.

DIENŒSTROL B.D.H. — may be prescribed for those patients who do not readily tolerate stilbœstro.

PARENTS IN CONFERENCE

A conference of parents (in which, however, the fathers were numerically insignificant) was held at Caxton Hall, Westminster, on March 18 under the auspices of the Federation of Committees for the Moral Welfare of Children. Mrs E M Lowe, JP, presided, and two preliminary addresses were given by Dr J A Hadfield, Lecturer in Mental Hygiene, University of London, and Dr Doris Odum.

"Treated as Mannikin"

Dr HADFIELD spoke of the mental and emotional development of the child, reminding the conference that the child was a different person at different stages of life. The child, he said, was too often treated as a mannikin, but in fact the child of 2 was quite different from the child of 6, and he again from the child of 12. The child of from 4 to 7 was an independent, unsociable creature, filled with a first sense of achievement, from 9 to 10, and again in adolescence, he was a member of a 'gang'. At about 15 he entered upon a romantic phase which was quite a different thing from the more sexual experience of 18. Dr Hadfield accordingly warned parents not to regard as abnormal many manifestations in the development of their children which were perfectly normal to their age and only temporary. It was natural for a child of 2 to be self-willed and for a youth of 15 to fall romantically in love. If such phases were checked they would persist into the ensuing phase and trouble would be caused. He pleaded for freedom for the personality of the child and the inculcation of the only discipline which was worth while, namely self-discipline. At least nine out of ten 'don'ts' were quite unnecessary. The human infant had fewer fixed reflexes than any of the animals and for that reason it was able to learn by experience.

Adoption of Children

Dr DORIS ODUM addressed herself to some of the practical problems which presented themselves to social workers. One of them was the question of adoption. Here no rule could be laid down, each case must be taken on its merits. There was a fundamental tie between child and mother, unique in human relationship and the child was likely to be happiest in contact with the mother, even if it saw her fairly seldom. But where the mother—she was thinking more particularly of the illegitimate mother with few resources—was of low mentality or in poor health or did not want the child, adoption was the necessary recourse. Safeguards were needed in choosing foster-mothers and it was better to be a little pessimistic than to be carried away by enthusiasm for adoption. Elderly people who had not themselves had children did not as a rule make good foster parents. Care must be taken not to create an 'only child' situation. It was important to acquaint the child from the start with the fact of its adoption, great psychological damage was done to the adolescent who learned for the first time that he or she had been adopted.

She next turned to the problem of enuresis. This had three origins (1, the smallest group) emotional, due to some lack of adaptation to the environment which led to reversion to an infantile level, (2) lack of training, (3) the largest group) failure of development of reflex control owing to some physiological defect. It could not be known in how many children this control was delayed, because the majority of children never needed to pass water in the night at all and so the lack of control was not suspected. In none of these three situations were the children blameworthy.

Speaking of sex difficulties Dr Odum said that it was almost incredible how early-Victorian was the average parent even in 1947. Parents still did not give their children anything at any age which could be called intelligible sex education. Very few mothers understood what menstruation signified or gave it any kind of biological value and they still looked with horror at masturbation in the very young child, being ignorant of the fact that the great majority of children grew out of it as they grew out of other physical habits with the advent of external interests. She pleaded for a far greater knowledge understanding, tolerance and sympathy on the part of parents.

Correspondence

Penicillin Black Tongue and Penicillin Stomatitis

SIR,—The discussion of penicillin black tongue and penicillin stomatitis in your recent issues prompts me to record my own experiences, which clarify some aspects of the problem. I have observed both conditions in patients treated by the inhalation of nebulized aqueous solutions of high-potency 'yellow' penicillin. On one occasion a black tongue was produced by peroral inhalation of four doses given 12-hourly, the total penicillin administered being less than 200 000 units. The patient was at the time taking 50 mg of nicotinic acid daily as a routine supplement to the standard post-war diet to which the nation is committed. Although such cases are of rare occurrence they impel one to the opinion that the buccal conditions are neither due to avitaminosis induced by the inhibiting action of swallowed penicillin on the nicotinic-producing bacteria of the gut nor due to the nature of the base used in the manufacture of pastilles, but are caused primarily by the local action of penicillin itself. If black tongue represents a specific disturbance of the balance of the saprophytes of the mouth, it should be possible to influence it in many ways. The saprophytic flora at any point in the body can be regarded as the biological reflection of the chemical and physical factors obtaining there. When pastilles are taken over a protracted period, the chemical nature of their base becomes an important environmental factor. It follows therefore that although penicillin initiates the processes which terminate in black tongue it should be possible to control the sequence for better or for worse by modifying the composition of the base—I am, etc.

Water and Salt Depletion

SIR,—I have read with great interest Dr H L Marriott's authoritative and stimulating lectures on water and salt depletion (*Journal* Feb 15 and March 8 and 15, pp 245, 285, and 328). During roughly the same period as when Dr Marriott was conducting his researches, I was also serving in India and encountering the effects of salt depletion in men who were being referred on account of psychological symptoms. While I am unable to quote statistical details it was obvious that salt depletion was either an aggravating or a primary factor in many of these cases. The main effects of low osmotic pressure which Dr Marriott quotes (p 286)—namely, lassitude, apathy, weakness, headache, and giddiness—are all symptoms liable to crop up in neurotic conditions, and there is little doubt that the term 'tropical neurasthenia' has been widely misused to cover the effects of salt depletion.

In his paper Dr Marriott describes a vicious circle of events in salt depletion (Fig 9, p 287) in which gastric symptoms such as anorexia and vomiting further reduce the body's supply of salt and I would like to point out another type of vicious circle which has certain psychiatric implications. Patients who had suffered from dysentery continued to have loose stools despite adequate drug therapy. The more outstanding cases often had a neurotic predisposition, but even when this factor was not distinguished the general effect of lowered morale coupled with the more obvious symptoms of salt depletion, produced a fertile ground for the seeds of anxiety. Morbid preoccupation over their debility and special concern with the presenting symptom (diarrhoea) led to a functional prolongation of the diarrhoea and consequent increase of salt depletion. The results of simple reassurance, a little mild sedation, and salt often had gratifying results. These measures may perhaps be equally applicable in certain other bowel disturbances irrespective of their exact origin.

Finally, there is one small point about which I would venture to disagree in part with Dr Marriott. He mentions the lack of thirst for salt as opposed to thirst for water. The animals who make periodic visits to salt 'licks' must have some biological urge in that direction. Further, I know from personal experience and from questioning others that in a state of salt depletion unsalted water tastes horribly insipid. This, of course, is not a positive appetite, but once realized does lead indirectly to a awareness of lack of salt—I am, etc.

Haywards Heath

A J GALBRAITH

Retrodisplaced Gravid Uterus

SIR—Through your columns I should be grateful for the opportunity of making some observations on the letters referring to my paper (Feb 1, p 169) written by my two friends, Dr M Hamilton (March 15, p 350) and Dr J A Chalmers (March 22, p 392).

Polak's figures quoted by me and those obtained at UCH show that sterility and retrodisplacement of the uterus are associated. This point was made in my opening paragraph and has been kindly enlarged upon by Dr Hamilton in his letter. What is not certain, however, is that the displacement in itself is the cause of the sterility. It is possible that there are other factors associated with the retrodisplacement which are responsible for the sterility and which are at present imperfectly understood. It is because of this that I have suggested that correction of the displacement in such cases should be left as the last method of treatment after all other treatments have failed.

I stated 'that the incidence of abortion in patients with retrodisplaced gravid uteri is at least no higher than that for all pregnancies.' The importance of the displacement as a cause of abortion has been overemphasized and is only likely to be a factor when it causes incarceration. These deductions were made on the figures obtained at UCH and on those of Danforth and Galloway quoted by me. Dr Hamilton, in his more logical manner, prefers to state that my figures "do not disprove the hypothesis that retrodisplacement (without incarceration) does not significantly predispose towards abortion." If the incidence of abortion (without incarceration) is not influenced by the position of the uterus then correction of the displacement is necessary only to avoid incarceration. I believe this applies to the primigravida and to the multipara, who may have had a previous abortion from a displaced uterus. Dr Chalmers disagrees with me on this last point and attempts to show that two of the three cases quoted by me prove his point.

From the history of patient No 39, Dr Chalmers makes the deduction that the ventrosuspension operation was unsuccessful and that the first two unsuccessful pregnancies occurred in a retrodisplaced uterus. Is this not putting the cart before the horse? The ventrosuspension operation was carried out at a reputable London teaching hospital (not UCH), and I am sure they would be as indignant at Dr Chalmers's "reasonable" deduction as he would be in similar circumstances. In any event, supposing the operation was unsuccessful, does not the case show that conservative treatment is possible and that continuity of the abdominal wall can be maintained? I would prefer to regard this patient as an habitual aborter, with the uterus accommodating the pregnancy for a longer period on each successive occasion.

In case 42 abortion occurred 11 weeks after anteversion had been attained (not 9 weeks as stated by Dr Chalmers). If circulatory factors dependent on the position of the uterus were the cause of the abortion as suggested, would the latent period be so long and would not abortion be much commoner than it is with incarceration when such factors are more likely to be active? Dr Chalmers has misread me when he says that I point out that circulatory abnormalities may interfere with the imbedding of the ovum in a retrodisplaced uterus. I only quoted Barnett's observation on the subject. Indeed, Barnett says that abortion due to such factors usually occurs at 2½ months, not 23 weeks. Personally I prefer to regard and treat such patients as cases of habitual abortion, and I admit that I do not know the cause of the abortion in the majority of such cases—I am etc.

London W 1

H H FOURACRE BARNES

Marrow Biopsy

SIR,—Prof D F Cappell, Dr H E Hutchison and Dr G Harvey Smith (March 29 p 403) call attention to the value of examination of specimens obtained from marrow by paraffin sections in addition to the usual smears. But their advocacy of a rather complicated and inevitably messy method of fixing the "mush" from the sternal puncture needle is surely out of date.

The Turkel trephine is little larger than the Salah needle and it permits of the obtaining of a 'sausage' of marrow as well as of the usual juice for making films. Essentially, it consists of an outer needle (with stylet), and a narrower inner one with a serrated end. The outer needle (with stylet in place) is pushed in until its tip sticks in the anterior lamella of the sternum. The stylet is then withdrawn and replaced by the inner (trephine ended) needle (also with stylet in place). When the end of the inner needle is in contact with the bone the stylet is withdrawn, and the inner needle is turned to and fro while slight pressure is exerted until a sudden cessation of resistance indicates that the medullary cavity has been entered, then a few more half-turns will fill the end of the inner needle with marrow. Next, leaving the inner (trephine) needle in position, the outer needle is pushed onwards in the marrow cavity. The inner needle is withdrawn and its contents expelled into fixative. A syringe is attached to the outer needle and marrow juice obtained by suction.

In this way marrow tissue is obtained while films are not diluted by aspiration of as much marrow as Cappell, Hutchison and Smith find necessary. In fact there is "at last the answer to the haematologist's prayer for a means of combining the advantages of sternal trephining with those of sternal puncture" (annotation p 419)—I am, etc.,

London W 1

A PINEY

Intrathecal Penicillin in Cerebrospinal Fever

SIR,—In his article on "Medical Aspects of Penicillin Treatment" (March 8, p 290) Dr B A Young expresses a doubt as to the necessity for intrathecal penicillin in meningococcal meningitis and also a desire to know the practice of few hospitals.

Speaking for the Park Hospital, I can say that the result obtained for many years with sulphonamides alone, especially sulphathiazole and sulphadiazine, have been so good that we consider intrathecal penicillin as an unnecessary complication in the routine treatment of these cases. Those who have had experience in the treatment of cerebrospinal fever in the past with meningococcal antitoxin have not forgotten the condition of patients receiving daily intrathecal injections of antitoxin serum, neither have they forgotten that often better results were obtained with intravenous administration alone. When they see the ease with which sulphonamide-treated patients now recover, they cannot help but view all return to unessential intrathecal medication as a retrograde step.

Moreover it is not sufficiently realized that the majority of the deaths from cerebrospinal fever at the present time occur in fulminant septicaemic cases, with or without adrenal haemorrhage and often with little or no evidence of suppurative meningitis. Intrathecal penicillin cannot help these patients. Intensive sulphathiazole treatment, combined with systemic penicillin for 24 hours, can save them. It is indeed a curious fact that since penicillin has become generally available the case mortality for cerebrospinal fever should have gone down. One can read in the introduction to the *Medical Annual* for 1946 "The limitations of penicillin are being recognized but it is surprising to find that sulphonamides may be superior to penicillin in the treatment of meningococcal meningitis."

It has become the practice apparently in many hospitals to administer penicillin intrathecally at the first lumbar puncture to all patients suffering from a purulent meningitis, whether primary or secondary and before a bacteriological examination. As at least 80% of all cases of primary suppurative meningitis are due to the meningococcus, this means that a large number of cases of cerebrospinal fever are receiving unnecessary intrathecal penicillin. This would not matter much if the injection was without danger. But even the purest penicillin, given with all precautions intrathecally, is often followed in infants and children by various reactions—twitchings, convulsions, apnoea, vomiting and collapse. In very ill cases with concomitant septicaemia it is easy to understand that the reaction may turn the scales against the patient.

During the years 1944, 1945 and 1946 136 cases of cerebrospinal fever have been treated at the Park Hospital and the case mortality for all ages all degrees of severity late and moribund cases included, has been 8.8%.

The value of intrathecal penicillin in suppurative meningitis secondary to otitis media, infected sinuses, cranial injuries, etc.

and also in primary suppurative meningitis due to the pneumococcus and many due to *H. influenzae* (Pfeiffer) is not questioned but in meningococcal cases its superiority to oral and systemic sulphonamides has not been established and its use is attended with unjustifiable risks—I am, etc,

London SE 13

L J M LAURENT

Epidemic Kerato-conjunctivitis

SIR,—The annotation on epidemic kerato conjunctivitis (Jan 15, p 145) prompts me to report the common occurrence of K P in an outbreak among British personnel in Calcutta in the rainy season of 1945

The usual history was of a sore eye 10 days after trauma occasioned by Rugby, soccer, or motor cycling without goggles. Swelling of the upper lid and of the pre auricular gland was present. Staining of the cornea with fluorescein developed a few days later, followed by K P in 20 out of 30 cases, sometimes with folds of Descemet's membrane and sometimes after the ciliary flush had subsided. The corneal picture bore a marked resemblance to the eye lesions of onchocerciasis, which of course, was not involved. The K P was as often associated with the type of fine corneal lesion as with the disciform type, and was quite a feature in this epidemic—I am, etc,

Johannesburg

J GRAHAM SCOTT

Endocrine Receptors in Relation to Cancer

SIR,—There can be little doubt that a living cell is ready and willing to receive an endocrine stimulus just as in plants and animals the female is ready and willing to receive the male element. But I fail to see why Mr T C Clare (March 22, p 390) labels a cancer cell as degenerate and therefore lacking in an endocrine receptor. A cancer cell is not degenerate by a very long way—it is, unfortunately, young, active, and vigorous.

For many years there has been an idea that cancer arises from some fault in the endocrines, the cell receptors or both, but prolonged observation and clinical experiment have failed to substantiate this theory, promising though it appeared to be.

We know that cellular division is the result of nuclear activity—the greater the nuclear activity the more rapid the cell division. And here we must hark back to the very beginnings of the organism. An organism was originally a small bit of our planet cast off when the latter began to cool. We are of the earth, earth. In the course of long years of evolution it adapted itself to surrounding influences, and ultimately man appeared. But just as in our planet, the earth, there are some atoms such as uranium, which are not too stable, so man may have some cells of a like character—liable to burst into exaggerated nuclear activity at slight provocation. Lucky are the people who have not inherited these unstable cells!

I submit, then that cancer is brought about by irritation whipping up the electrical phenomena known as nuclear activity in cells which happen to be unstable. If this be so, what then? The Ministry of Agriculture has forbidden the propagation of plants which are liable to disease—for instance some varieties of potato. Breeders of animals and birds choose healthy parents. As this naturally is impossible in the human race the predisposition to cancer will continue to be handed down—I am, etc

Wigan

J THOMSON SHIRLAW

Amoebic Hepatitis

SIR—During the last few months there have been admitted to my wards four cases of hitherto unsuspected amoebic hepatitis with abscess two of them fatal. One gave a history of treatment with emetine in 1920 in India and two others admitted to fleeting attacks of diarrhoea in the Far East, while the fourth assured me that he was the only soldier in the Middle East who had never had an attack of diarrhoea. A fifth case sent in for diagnosis for axillary glands was found to have a tender liver and the sigmoidoscope revealed advanced amoebic ulceration of the bowel. This man had been in the Navy and had had attacks of diarrhoea on and off but never enough to report sick.

As such a large part of the British Army served in 'amoebic countries' in the late war and as the original infection by the *Entamoeba histolytica* can be such a mild disease, it seems to me that such cases may become common during

the next few years, and practitioners should keep a careful watch for them. Admittedly the signs and symptoms of early amoebiasis of the liver are indefinite and are not confirmable by laboratory tests. In a doubtful case, however, the improvement with emetine is dramatic if one is on the right track. Few diseases are more treatable in their early stages, but if not diagnosed in time disaster may easily follow—I am, etc,

Bristol

RICHARD C CLARKE

Arsenical Encephalopathy

SIR—The case report by Drs G Hipps and R Goldberg (March 8, p 296) on a patient dying with arsenical encephalopathy calls for some comment. Their treatment was that advocated by Ransome *et al* (1945)—i.e., the patient is sat up in a vertical position, receives calcium gluconate, calcium thiosulphate, vitamin C, intravenous glucose-saline, and is repeatedly lumbar-punctured. Stress is laid on the postural part of therapy in order to decompress the brain.

Whereas it is obviously difficult to be dogmatic in a condition which is rare and where spontaneous recoveries occur (mortality is estimated at 75%), the promise of British Anti-Lewisite (dubbed BAL by the Americans) appears to be considerable in reducing the mortality in arsenical encephalopathy. In a recent survey by the American Council on Pharmacy (1946) 44 out of 55 patients suffering from arsenical encephalopathy recovered after receiving BAL, of the 11 cases who died 5 were started on this treatment some 9-72 hours after coma had set in. Thus with early administration of BAL one may hope to reduce the mortality to less than 15%. The American Council recommends 3 mg/kg four-hourly intramuscularly for two days, then four injections on the third day and two injections on the following days until the patient has completely recovered. They emphasize that BAL must be given early and in adequate concentration to be of use.

My own experience is confined to two patients, both of whom recovered with BAL as the principal therapeutic agent although both were comatose when this treatment was begun. Incidentally the first patient was nursed flat on his back, the second sitting up. In view of the published results of the American Council it is considered that BAL should be the primary agent in treating patients with arsenical encephalopathy—I am, etc

Electric Convulsion Therapy

SIR—During the past nine months a new technique for the administration of oxygen and CO₂ throughout the convulsion has been used in the out-patient ECT clinic at St George's Hospital in an attempt to reduce the excessive cyanosis produced by the convulsion, with the resulting stress upon the cardiovascular system.

It has been our practice over many years to administer oxygen through a Hewett N O and O₂ mask at the conclusion of the convulsion, and in this way to cut short the period of cyanosis as much as possible. However, it was felt in the case of old patients (a number being over 70 years of age), and in plethoric and hyperpneptic subjects and in those suffering a degree of cardiac insufficiency, that the less strain that could be placed upon the cardiovascular system the better. With this object in view, it was decided to administer oxygen throughout the convulsion. This at first sight may appear illogical in view of the supposed laryngeal spasm occurring at that time, in actual fact, however, this spasm seems to take on the characteristics of the general clonic contractions and in reality is only intermittent—this can be observed by watching the bag of the apparatus when oxygen is administered throughout the convulsion, it will be noticed that very shallow and rapid respirations are taking place in time with the convulsions.

That gaseous exchange is also taking place is demonstrated by the fact that at the end of the clonic phase, and before normal deep respirations are resumed, the patient will be seen to be a good colour with little or no evidence of cyanosis—this being a marked contrast to those cases which do not receive oxygen during the clonic stage.

The technique observed is as follows. The current is administered in the normal manner, after the original muscular contraction and cry it is rapidly verified that the mouth gag is in correct position, has not shifted, and is firmly gripped. A Hewett gas and oxygen mask is then immediately placed over the mouth and nose and kept firmly in position, the mask should be of sufficient size to cover the No 9 size rubber gynaecological ring used as a mouth gag. The oxygen is turned on and the administration is continued throughout the clonic phase and until the patient has taken two or three normal respirations.

With this technique cyanosis is avoided, thereby reducing cardiovascular stress and allowing a wider margin of safety, at the same time the impression gained by this observer is that there is a reduction in distress experienced by the patients on recovery from the convulsion.

I should like to thank Sister B N Samuel for her efficient running of the ECT clinic—I am, etc,

London SW1

S M WHITTERIDGE

Control and Treatment of Diphtheria

SIR,—Dr James Fanning's interesting account of an outbreak of diphtheria in a girls' school and your excellent leading article on the control and treatment of this infection (March 22 pp 371 and 384) both draw attention to the necessity for boosting doses of prophylactic at regular intervals during childhood and the school years. Insufficient attention appears to have been paid to this latter aspect of diphtheria control by the propaganda departments of public health authorities, and when this weakness in a child's protective armour is pointed out one is frequently confronted with the parental argument that their 7-year-old is immune because he was injected at the age of 1 year.

There is little difficulty in obtaining permission to revaccinate the school child, but the public still requires considerable education before it will accept the idea of reimmunization to diphtheria, and it is hoped that your leader and Dr Fanning's article will direct the efforts of public health authorities towards this end—I am, etc,

East Horsley Surrey

BASIL S GRANT

Treatment in Early Cases of Influenza and the Common Cold

SIR—For the past three years I have been treating successfully cases of influenza and the common cold by intravenous injections containing quinine bihydrochloride. Cases of the common cold subsided within 12–48 hours after a single injection of 2 gr (0.31 g) quinine bihydrochloride dissolved in 2 ml of normal saline, while cases of influenza subsided within 2–3 days with the same injection and repeated within 12 hours. A number of cases were specially recorded during 1946 and a large majority of them responded successfully. Of course I am referring to cases seen within the first 24 hours. The object of this report is to interest investigators of this universal malady.

Virchow (1927) thought there might be a small decrease or increase in gaseous metabolism. Hardikar (1925) also noted a change in metabolism. Brown (1912), Solis-Cohen, Kolmer, and Heist (1917) noted that quinine is quite bactericidal to pneumococci *in vitro*. Probably quinine acts by checking the abnormal metabolism which is going on during the infection, or it may be that it interferes with the action of the virus concerned—I am, etc,

Technique of Venepuncture

SIR—Further to Dr J A M Cameron's remarks on venepuncture (March 29 p 425), I have found the essential points to be (a) efficient local anaesthesia, (b) complete extension of the arm at the elbow and supination of the forearm, (c) congestion of the veins of the forearm by a constriction higher up the arm at about 70 mm Hg pressure (d) decision as to site of puncture to be made by palpation rather than inspection, (e) at the moment of insertion of the needle, traction to be made on the skin distal to the site of entry and at the same

time the patient or donor to be asked to clench the fist, (f) attention to sharpness of the puncture needle.

I have found an oblique light shining on wet skin to be most helpful in demonstrating a slight convexity of the skin due to a palpable but not otherwise visible underlying vein, and when ever possible I try to avail myself of this aid, but do not regard it as essential. In many cases a suitable vein is plainly visible without this aid, and in most of the others the course of the vein will be identifiable by the palpating finger. In less than 0.5% of adults the only superficial veins are very small and close to the surface. No larger vein is palpable, and evidently most of the return circulation from the hand and forearm is by vessels deep to the bicipital fascia. This condition is not always bilateral, and both arms should be examined, but where it is I do not regard these persons as suitable for venepuncture in the antecubital fossa. I agree with Dr Cameron that attention to stance is of prime importance for successful results—I am, etc

Cambridge

C B V WALKER

Sphygmomanometer Armlet as Tourniquet

SIR—The daily Press recently reported a case in which a tourniquet was not removed from a patient's leg following a operation, and in which the mishap had a fatal termination. I have for some time employed in orthopaedic operations, requiring a tourniquet a simple apparatus connected with an ordinary anaesthetic machine, by which an inflatable sphygmomanometer armlet is connected by tubing to a reducing valve on the CO₂ cylinder. The latter is adjustable to give pressures between 150 and 250 mm Hg, and since the exact pressure maintained does not much affect the use of the gas for anaesthetic purposes, the supply is made by a branch tube both to the armlet and to the flowmeter of the machine.

The apparatus is indicated in the accompanying rough sketch and has proved of real practical use. One becomes at once independent of the minute leaks which seem an inseparable feature of such pneumatic systems, and the surgeon is spared the irritation of the pressure running down in the middle of the operation. Above all, it is impossible for the patient to come to some mischance to be returned to the ward with the tourniquet still in action.

Some modification of the commonly used reducing valve and armlets is of course necessary for the use proposed, and unfortunately there does not appear to be any commercial source of such apparatus. I am, however, making inquiries with a view to their manufacture, and hope to write later when a more finished type of apparatus is available—I am, etc,

Wallasey Cheshire

R L WYNN

Control of Leprosy

SIR—In the interesting leading article (Nov 2 1946 p 65) on the control of leprosy occurs the statement "It soon became evident that compulsory isolation had become worse than useless." At first sight this remark from its context, might have been regarded as applied to India alone, but when coupled in the same article with a disparaging reference to "the Biblical and Middle Ages plan of compulsory segregation" and a later contrasting mention of "modern methods" it is evident that it was intended as an authoritative statement of the present position and that by the up-to-date person the policy of compulsory segregation should be regarded as a futile anachronism.

Having been advocating and carrying out a policy of compulsory segregation for the control of leprosy in Fiji and the neighbouring islands of the Pacific since 1930, I am naturally interested in the

applicability or otherwise of your editorial comments to our work in this part of the world. It may also be of interest to your readers to know how the condemned policy actually works in the Pacific Compulsory isolation of lepers in Fiji started in 1911 with the establishment of a small 'asylum' on the recently purchased island of Makogai. Up to the end of 1946 738 patients or over 25% of the 2845 admissions had been discharged as 'arrested' (having shown no sign of leprotic activity for at least 2 years) in addition to 436 improved patients, many of whom would have undoubtedly gone on to arrest under continued treatment but who were repatriated to India at their own request.

In a comparative study utilized in my handbook on Makogai, published in 1944, and reviewed in your columns I pointed out that during the 24 years from 1919-43 our numbers had increased by 92 or 0.07 per thousand of the population, but that study of the types and stages admitted in each of the two years mentioned showed a marked improvement. Thus in 1919 there was not a single case admitted in the early non infective neural-1 stage, in 1943 27% of the cases were neural 1. In 1919 24% of the admissions were hopelessly crippled and deformed neural 3 cases, as against only 3% in 1943. In 1919 32% of admissions were in the highly infective and advanced lepromatous-3 stage there were none in 1943. Regarding these results I commented: Prejudice, compounded mainly of ignorance and fear, natural in the early stage of a policy of segregation, has largely broken down. Discharged cases averaging about forty a year over the past ten years provide the best form of propaganda, both as to the good living conditions at Makogai and as proof that segregation is not necessarily life-long.

More than 60% of our patients are lepromatous and infective—the type for which your leader-writer advocates isolation 'with little or no compulsion'. The suggestion is of course that if we improve conditions, increase amenities, and make the leper colony a real 'home from home,' patients will be so attracted that there will be little need for compulsion. This is very largely a delusion. At Makogai patients are better housed, fed and clad than they have ever been in their lives and are given the best available 'modern' treatment. They are provided with churches, schools, (all) theatre complete with stage etc., and their own co-operative store. They are paid for their garden and fishing produce as well as for the many jobs of maintenance of roads and buildings they are enabled to do. There is no question as to their appreciation of all these amenities and they are on the whole a contented community, the element of compulsion being kept well in the background and needing to be invoked on rare occasions only. It is quite certain though that their knowledge of any relaxation of the law under which they are segregated would definitely unsettle their minds, and although the large majority of at least the more advanced cases would undoubtedly wish to return, most of them would want to 'test their freedom' by visiting their relatives from time to time and for variable periods and so nullify the whole desired effect of isolation.

With regard to the remaining 40% or less "non infectives," the difficulty of transport to and from the forty-odd islands from which our patients are drawn would necessitate the use of a few only of the main islands for the establishment of the proposed outpatient clinics with the result that a large proportion of these patients would still have to be uprooted from their island homes and families. Fiji thus presents a very different problem from that of the solitary island of Nauru with its 70 square miles of total area whose serious epidemic is quoted, apparently as an example of what should be done in the South Pacific. Knowing that compulsion was no longer available to enforce their attendance, many of our natives would certainly refuse to exile themselves in this way—at least for any prolonged course of treatment such as is necessary for leprosy. Being liable at any time to pass into an infectious stage they would thus constitute a continual danger to the public.

In his report on a 'Health Survey of the British Solomon Islands Protectorate' Dr S. M. Lambert, representative of the Rockefeller Foundation, comments on the Leper Hospital on the island of Malaita. They have 71 lepers in the colony at present; they have seen 194 lepers; they have had no arrested cases. The result is growing but they have no legal hold on the native. He may come in for a month and then he may not be seen again. They cannot compel them. Dr Macpherson in charge of the leper colony, told me that at Quibuta the average term of residence of a leper is four weeks. He mentioned (S.M.O.) agrees with the experience of Macpherson that the principal trouble is that the natives expect to see the same result for leprosy as they do for syphilis. If they do not improve after three needles they leave. This is of course the great weakness of attempting to treat leprosy with chemotherapy powers. I have heard the same complaint from leprosy workers in India and elsewhere everywhere to persuade the reluctant patient to stay the course. The prolonged method of treatment required often why? Any very obvious improvement may be easily discouraging to the victims and is

is asking too much of all but the most intelligent and persevering to continue to submit to an indefinite series of injections if the choice is left to them.

In conclusion I would like to emphasize that this letter is merely a protest against the assumption that because a policy has been found impossible or inadvisable in certain areas it is thereby necessarily to be condemned everywhere. I would submit that in Fiji we have attained and are attaining, under the existing policy results that would be impossible under a voluntary system. It is gratifying to note that a review in the current *International Journal of Leprosy* just received, refers to our 'humane and efficient system' at Makogai. In the same way, therefore, as we have learnt to treat the patient rather than his disease, so must we determine our medical policies in the light of local circumstance and not by rule of thumb—I am, etc.

Central Leper Hospital
Makogai, Fiji.

C. J. AUSTIN

Peptic Ulceration

SIR—I have been reading the recent correspondence on peptic ulceration with interest. Attention seems to be mainly focused on diet, intermediate feeds, alkalis, and surgery. Vitamin C is thrown in. Bilateral vagotomy is mentioned. Too little attention is paid to the psychological element, for psychoneurotic causation seems to me to be present in the majority of cases of chronic ulcer.

In the course of five years' practice I believe I have treated perhaps a hundred cases without ever having to admit defeat by seeing one of them undergo operation.

The treatment is the usual diet, two-hourly intermediate milk feeds, and alkalis. In all cases with a psychogenic aetiology, partial or total phenobarbitone sodium, 1/4 gr (16 mg) or 1/2 gr (32 mg) is given in each dose of mist mag trisilicate. Occasionally tr belladonna, 5 minims (0.3 ml), is added to the alkali. The advantage of including the phenobarbitone in the medicine is that it can be introduced and withdrawn without the patients' knowledge. This to my mind is of paramount importance in treating the psychoneurotic. It is possible to cure the ulcer and then the residual symptoms of pain while dealing with the psychological element by phenobarbitone and so to break the vicious circle. When residual symptoms have subsided with the patient's confidence in himself increased in direct proportion to his weight it is then possible to withdraw the phenobarbitone while continuing the alkali. His medicine is by this time the pillar of the patient's strength but once the phenobarbitone is withdrawn (without his knowledge) the patient becomes less dependent on his medicine and eventually this can be withdrawn. Why he becomes less dependent on his medicine he doesn't know, but to him it implies final health. Dieting is maintained for some months or perhaps indefinitely.

I have found that this method of treatment produces more rapid healing from the day the x-ray diagnosis of ulcer is made to the day x-ray proof of healing occurs than by any other method—I am etc.

Hampton Hill, Middlesex

I. E. D. MCLEAN

Solitary Prolapsing Thrombosing Piles

SIR.—It has been my practice for the last couple of years to ligature and excise solitary thrombosing prolapsing piles which are giving rise to severe symptoms and do not respond rapidly to palliative treatment. The excision is done under local anaesthesia and mostly in my surgery. The dissection follows the St. Mark's Milligan and Morgan method generally. In some the longitudinal muscle band is reluctantly divided in order to free the pile sufficiently to obtain a ligature of the uninvolved pedicle. Stout linen suture is used. The excision is only done in the clean thrombotic stage and in the early ulcerative stage with no gross signs of inflammation.

Many patients are saved from the strangulation and consequent gangrene of this complication with its prolonged severe pain. Sulphadiazine 3 g is given one hour pre-operatively with sodium bicarbonate and 1-g doses four-hourly with sodium bicarbonate are continued for six doses—I am etc.

Johnsburg,

STEPHEN EISENHAMMER.

Child Guidance

SIR—Prof Cyril Burt invites discussion in his article in the February issue of the *British Journal of Educational Psychology* May I offer a little?

(a) He writes "So far as the children are concerned what is needed in most instances is not psychotherapy or treatment but character training, re education, and remedial coaching. This puts his finger on what is probably the greatest weakness of modern child guidance—namely, the practice of psychotherapy on children where none is required. In Surrey the policy adopted is that of Prof Burt, direct psychotherapy with the child plays only a minor part in my clinics. But what is 'character training' in a child whose school and home training have failed to prevent him reaching a child guidance clinic? It is something which is certainly going to involve intensive treatment (analytical, persuasive, and so on) of the mother sometimes of the father and sometimes of the brothers and sisters. Why does Prof Burt skip this point to reach his conclusion that "the problem of child guidance is not so much clinical or medical but psychological"? Is it because in many clinics the so called treatment of the mother is done by psychiatric social workers?

(b) He adds that "the psychologist" should have a training in the home conditions of the people. The psychologist is much too specialized for this. Only an experienced general practitioner knows sufficient of the intimate life of people to make eventually a really good child psychiatrist. Prof J A Ryle of Oxford, this month has emphasized the importance of this side of "social pathology" in an address to the New York Academy of Medicine. (The child psychiatrist must of course be trained as well in psychiatry.)

(c) Prof Burt insists also that there should be two types of child guidance clinics—one medical and one educational. In this he has formidable support in Dr Blacker, and more recently the powerful subcommittee of the regional medical advisory committee of the Nuffield Provincial Hospitals Trust have made similar recommendations. On the other hand against this three-headed dragon there stands so far alone like St George, Dr Bowlby, who at an interclinic meeting of the National Association for Mental Health pronounced against this view.

On paper the dragon has it, but in practice they will find their scheme rather difficult. It will work in small areas like county boroughs, but it will break down in larger areas such as the counties. In Surrey we are once again rather ahead of the planners—we have the dual scheme at work but it is under one administration only—the public health department. A child psychiatrist visits school clinics and hospital (St Helier County Hospital). There are no psychiatric beds but the child psychiatrist visits the children's wards when requested by the paediatricians. He sees patients in the hospital from the schools as well. The enemy to the Nuffield subcommittee's scheme is geography. To have double administration clinics would present innumerable difficulties. (I wonder how many of the Nuffield subcommittee are actively engaged on child psychiatry requiring county organization.)

(d) The most practicable scheme in the large areas is for the education department to refer cases requiring psychiatric advice on paper to the child psychiatrist through the school medical department, and much of what happens after that will depend on where the child lives. The geographical position of the child's home is going to play a greater part in determining which child guidance clinic he will attend in the first instance than will the actual diagnosis. That is why Prof Burt's recommendation to divide cases into "normal" cases and "pathological" cases is an impracticable one even if his meaning were clear on this point.

(e) If the academicians are not careful they will drive more child guidance into the out-patient departments of mental hospitals—an action which is analogous to treating early surgical conditions of children in the out-patient department of a cancer hospital.

I agree with Prof Burt's idea that child psychiatry should be a branch of paediatrics, but I also agree with Prof D R McCalman's statement (made some years ago) that elasticity in local development should be allowed—I am etc,

JOHN A McCLUSKIE

Kingston-on-Thames

Shortage of Nurses

SIR—May I beg a little space to answer the letters of Miss Evelyn C Pearce and Miss C Morfee (March 29 p 424)? To take Miss Pearce's letter first. I am well aware of the establishment of training colleges for nurses and have repeatedly examined candidates from these schools who are well marked by the fact that they do not appear in uniform. I regret to state that though these girls seemed of a better type, they were in general considerably worse taught than candidates coming from hospitals, who had been under sister tutors. I can remember one group who had never tested urines, and another group who were completely ignorant of all the digestive ferments. I have yet to learn that the State is subsidizing these schools and pupils, which I have submitted is the only way to get satisfactory recruitment. If the State is not doing so, then I am afraid Miss Pearce has missed the real point of my letter—that is, that the State must keep these girls from their school leaving age to the time they are old enough to enter hospital.

Miss Morfee's complaint that nurses are used as messengers seems merely *une raison de plus* for discontent, and rather a trivial one at that. Nurses, after all, are meant to be useful and they have been relieved of a great many of their more menial duties. Is it too much to beg for a correction in my original letter? "They would pass examinations each year and be eliminated and passed on for another year" should read "They would sit for examinations each year and be eliminated or passed on for another year—I am, etc,

Great Yarmouth

LEONARD LEY

SIR—Nursing could be made more attractive to girls if they were not under discipline in their hours of rest. The hospital houses its nurses largely for its own convenience, but there is no reason why they alone of almost all employees should have to be under the authority of their employers when they are off duty.

In Sweden the nurses run their own homes through a committee and thereby have a feeling of greater freedom. Nurses still grumble about their food, but if they were allocated their rations and invited to devise their own menus I feel that these complaints would soon cease, particularly if the most inveterate grumblers were put on the menu committee. In the magnificent new hospital in south Stockholm they have gone one step further, and any nurse who wishes is allowed to live in the city, a small nurses' home being retained so that they may have a nucleus of nurses to fall back on in emergency. This seems to me the ideal to be aimed at for our future hospitals—I am, etc,

Colchester

M E LAMPARD

SIR—In reply to Dr Leonard Ley's letter (March 15, p 355) I see nothing "revolutionary" in any of his proposed changes half of which are already in existence. The urgent need for intelligent people to take up the work is well known, but having entered the nursing profession they find their intelligence insulted by people like Dr Ley, who infers that they are incapable of managing a private life (I can find no other interpretation of "racketing about half the night"). A nurse's job is certainly an arduous one, but no more so than countless others where the lives of many depend upon alert minds—e.g., bus and train drivers, etc. Does anyone question the hours they keep?

As for the nurses' exposure to ill health, I believe that doctors take the same risks. It would be well for the powers that be to ponder awhile on 'freedom after work'. Who knows, it might prove to be the answer to "why no nurses"—I am, etc

London SW 17

EDITH RICHARDS

First Things First

SIR—The conclusion of Mr Malcolm Donaldson's letter (March 22, p 388) that "it takes four years to train a nurse" is open to question. Increasing support goes to the two tier plan of a 2 years concentrated training for State registration followed by graded post-certificate work for those who aim at the higher services of administration or specialized work including the ward sister's.

You Sir by giving columnar priority to Dr Donaldson's letter for First Things First would seem to agree that the nursing crisis ranks high even among its many competitors on day but is it really the housing aspect that places it in such pre-eminence or wider considerations?—I am, etc.,

ESTHER CARLING

Moor Park, Northwood

An 84-hour Week

SIR—Perhaps I owe Dr G Rosemont an apology for failing to see certain of the subtler implications in his original letter (Feb 8 p 233). The point, then, is this that the National Health Service, which is intended to provide the nation with an efficient smooth running bigger, and better health service than it has or ever had, proposes to do this by demanding—and if need be enforcing—a 24 hour daily service from its doctors? There is no trade, profession or occupation in the most servile state that would dare to make such a demand of its workers and get off with it. If as Dr Rosemont asserts, this is the intention of the Minister, then I entirely agree with him that the Minister will be justified in enforcing it 'if we sign the contract'.

Granted, no doctor will be called upon to work continuously for 24 hours, even so, he should not be required to hold himself in readiness for service during 168 hours, which make up the calendar week. Dr Rosemont suggests that it should be the duty of the Minister to provide an emergency night service. I return to my original point—which was rather neatly sub edited, saving your presence!—that adequate leisure should be ensured the G.P. by the official provision of emergency services available on Sundays, half-days, and holidays. No doctor serving under the NHS scheme should be required to supply a substitute at his own expense during sickness or holidays, and every doctor should be entitled to at least one free day in the week. If the NHS scheme cannot provide these minimal amenities the improvement in the health service to the community will prove theoretical rather than actual—I am, etc.,

Edinburgh

R DINGWALL KENNEDY

SIR—Doctors are men of honour, and we should not agree to take on obligations that we are not able to perform. To-day, labour is impossible to obtain—for example although I have kept my car for 20 years in a public garage, yet for the past two months I have had to dig my garage doors free of snow because modern apprentices do not do labouring work. I can never get the car washed so scarce is labour.

Our wives are not our slaves. Does Dr G Rosemont (March 22 p 391) suggest that we should compel them to be on duty answering doors and phones for such hours as no paid servants would work?

I recall during the past nine months 15% of the panel practitioners have resigned to take up other work. Moreover, do not our present working conditions bring us a higher death rate (the Spens Report p 5)? Is this high death rate to be perpetuated?

The terms of service for G.P.s must be national and the hours must not exceed a just week's work. The responsibility for the 24 hours service must be the Minister's not the individual doctor's otherwise the scramble to get out of G.P. work will become a deluge—I am etc.

G D SUMMERS

Rates of Pay

SIR—I think it is true that the increased rates of pay in the Army have been largely wiped out by a juggling with allowances and a different interpretation of what is and what is not taxable. Though heralded in the Press as an improvement in pay, the new arrangements have borne hardly on those affected. Possibly they cannot strike they cannot organize or refuse and they are denied access to the correspondence columns of newspapers except anonymously.

Since they are employed by the State they cannot sue the Government. It is possible when the Crown Proceedings Act is passed that this is another example of can about democracy and freedom from fear and want but it has served to prevent doctors in the new

Health Service from being treated similarly, and what remedy would they have? In my opinion they would have none—I am, etc.,

Colechester

G C PETHER

The Pemmican B.M.J.

SIR—On behalf of my Association I would congratulate you and your staff on the sterling effort you have made to keep up the circulation of the *British Medical Journal* in spite of the extreme difficulties which you have had to face.

Colleagues in South Africa have a deep sense of appreciation of the courage of the people of Great Britain which their efforts during the war aroused. Their courage in the present crisis has done much to extend our admiration, and this effort of the British Medical Association, though small when compared with the background, has done much to illustrate the qualities which we so much admire—I am, etc.,

A H TONKIN

Medical Secretary

The Medical Association of South Africa

Capetown

SIR—We commend the courage and resourcefulness which produced the Candle-Light number of your famous *Journal* and we shall treasure the copy which has come to us. We have read over here with mingled feelings of pity and distress of the difficulties to which England has been subjected by the recent vagaries in your weather conditions, although possibly they must be regarded as more than vagaries when they produce such absolute paralysis as has been visited upon your country. Let us all hope that the situation may never be repeated.

With all good wishes, believe me,—I am, etc.,

GEO W KOSMAK

Managing Editor

New York State Journal of Medicine

New York

SIR—Here, in the lush, centrally heated warmth of my consulting-room, by the bright fluorescent lights on my ceiling fixture and the warm glow of my desk-lamp, I read the March 1 edition of the *B.M.J.* (the manually produced one). My heartiest felicitations and admiration to my British colleagues for their grand spirit in carrying on despite all adversity! Being Scottish-trained I can understand the rugged times you must be having now.

The *Journal* helps to keep the old ties to Britain burning for me and, I'm sure many others. Carry on, and let's hope your troubles are soon over—I am, etc.,

New York

SEYMOUR TENZER

SIR—Received this date (March 11) the *B.M.J.* of Feb 22. May I thank you for this valuable souvenir. In years to come I can look upon this as evidence of your country's trials in 1947. The prosperous and influential Empire and Commonwealth of that future date will have given the lie to those who predict its dissolution to-day. We, who were with you in 1940 know that you will win through this trial also—I am, etc.,

Wakefield, Canada

J H S GEGGIE

SIR—At a meeting of the West Sussex Division of the B.M.A. last Wednesday the following resolution was passed:

That this Division desires to express to the Editor of the *British Medical Journal* its appreciation of himself and his staff for their efforts in producing the pemmican *B.M.J.*—I am etc.

Worthing

R H WILSHAW

Hon Secretary

* * We print above a further small selection from the many letters on the Pemmican issues of the *Journal*—Ed. *B.M.J.*

It is estimated that there are 150,000–200,000 people with cerebral birth palsies in the United States. About 70% can be educated. Psychiatrists emphasize that it is the parents who must play the most important part in bringing up these children. The Michael Reese Hospital at Chicago maintains a day nursery to which parents can take palsied children and where they receive instruction in continuing the children's training at home. Orthopaedic and physiotherapy departments are available for physical defects.

Obituary

W T MUNRO, MD, FRCPEd

The death of Dr William T Munro, which took place at Perth Royal Infirmary on March 11, after a long illness, removes from our midst one of the leading British authorities on tuberculosis. He was born at Frickheim, Angus, in 1884, and was educated at Arbroath High School and the University of St Andrews, where he qualified in 1908, proceeding MD in 1912. He obtained the DPH in 1914, and was made a Fellow of the Royal College of Physicians, Edinburgh, in 1929. Shortly after his retirement the University of St Andrews, in June, 1945, conferred on him the honorary degree of LL D.

Dr Munro was resident for a time in Dundee Royal Infirmary, and later went to the Sidlaws Sanatorium, Auchterhouse. The 1914-18 war interrupted his work, and it was in 1920, after a period of service in the Army, that he was appointed medical superintendent of Glenlomond Sanatorium. There he remained for twenty five years, until ill health forced him to retire in 1944 at the early age of 60. The sanatorium had been open for only a little over a year before Dr Munro took charge there, and that the name of Glenlomond became widely known was entirely due to his work. He was not content merely to be a medical superintendent, busily engaged with problems of administration, diagnosis, and treatment. He had an active and inquiring mind, constantly concerned with the elucidation of the many problems of tuberculosis. Much research work was done during his tenure of office at Glenlomond, and in all he contributed some thirty papers to medical and scientific journals. His outstanding achievement was his work on the bovine tubercle bacillus as a not infrequent cause of pulmonary tuberculosis in man. This led to his association with Dr Stanley Griffiths and a long and fruitful collaboration in connexion with the incidence of pulmonary tuberculosis of bovine origin. In later years Dr Munro was greatly interested in the mode of spread of tuberculosis in infected children. His deductions on this point did not meet with universal acceptance, but he would probably not have expected it to be otherwise. An enthusiast, always questing for the truth, he did not accept his own findings as final. At times a severe, if never unfair, critic, he was always prepared to meet criticism of his own opinions. He took an active interest in the National Association for the Prevention of Tuberculosis, and was one of the most prominent members of the Tuberculosis Society for Scotland, which he represented on the Joint Tuberculosis Council. After he left Glenlomond he continued as consulting physician to the Bridge of Earn Hospital, and took an active part in discussions and meetings of the Tuberculosis Society until a few months before his death. On his last attendance there, and when obviously a very sick man, he made a spirited plea for the recognition of all the manifestations of tuberculosis as one disease and deprecated the present tendency to regard respiratory tuberculosis as a separate entity. A keen intellect, great enthusiasm, and tenacity of purpose were probably his outstanding characteristics. Socially, to those who knew him well, he was generous and kindly, with a fund of entertaining anecdotes. He was ever ready to help and to impart knowledge to his younger colleagues, and many men must be grateful for his instruction and guidance. His contribution to our knowledge of tuberculosis is unquestioned, and for that he will be gratefully remembered.

H MUIR EVANS, MD, FRCS

Dr H Muir Evans, who died at the age of 80 on March 28 at his home at Beccles in Suffolk, combined the life of a successful busy general practitioner with that of a research worker in biology, in this way following the example of many distinguished predecessors. He was a Fellow of University College, London.

The third son of Mr George Evans, of Richmond, Surrey, Harold Muir Evans was educated at Bute House, University College Hospital, and Berlin University. He took his conjoint qualification in 1889, the London MB in 1890, and the MD in 1893. In 1939 he was elected F.R.C.S. England

as a member of the College of more than 20 years' standing. After serving as a house surgeon at University College Hospital he was for two years medical officer for the Cape Government railways on the Bloemfontein Vaal River Extension, and on return to England served for a time as registrar to the Central London Throat and Ear Hospital. In 1894 he began work as a general practitioner in Lowestoft in Suffolk, and continued in practice there until a few years ago. Probably reasons of health determined his choice of a seaside resort on the East Coast in which to spend his professional life. There can be little doubt that his exceptional mental and professional gifts would have secured him a distinguished place in consultant medicine if he had chosen this type of work as his career. From boyhood Evans was a keen fisherman and sailor, and he found these hobbies led him into the paths of natural history of most interest to him. One of his early pieces of research was into the poison glands of fish. Communications by him on the defensive spines of fishes and on the anatomy and physiology of swim-bladder and Weberian ossicles in Cyprinids were read before the Royal Society. In 1940 he published a book entitled *Brain and Body of Fish*. The reviewer of this in the *Journal* (May 18, 1940) wrote "There can be no doubt that the author's method of studying the correlation of function and structure is profitable from the anatomical point of view, for it does provide valuable clues to the significance of neural mechanisms which might otherwise be quite obscure."

It is a book which not only will be useful to the comparative neurologist but must also be read by all those who make a study of fishes." The reviewer referred to Evans' book as an outstanding manifestation "of the real spirit of scientific inquiry still occasionally to be seen." In 1943 Evans published a delightful book entitled *Sting fish and Seafarer*. Another example of his work in biology was a paper on the pituitary gland of the eel, published in the *Journal* of April 6, 1940, in which he traced the seasonal changes in the morphology of this gland. Three years' research showed him that in the last two months before migration there was a great increase in the size of both anterior and posterior lobes of the eel's pituitary. Evans was an accomplished amateur painter and illustrated his papers and books with his own pen. In the war of 1914-18 he served with the rank of major as surgeon specialist in clearing stations. He was always keenly interested in the work of the B.M.A. and served at different times as Representative, as Chairman of the North Suffolk Division, and as President of the Suffolk Branch. He was Consultant-Surgeon to the Lowestoft and East Suffolk Hospital and had a wide practice and sound reputation as a general practitioner surgeon.

Muir Evans was distinguished in person as well as in mind and at times found it difficult to suffer fools gladly. He used to say that he gave nine-tenths of his life to his profession and the remaining one-tenth to his hobbies, and his primary hobby was that of a research worker in field biology. His death removes from medicine a general practitioner who represented a type of medical man now become unfortunately rare in these days of scanty leisure and extreme specialization. He is survived by his widow, two sons, and a daughter, to whom our sympathy is extended.

WALTER RAMSDEN, D.M.

Dr Walter Ramsden, Senior Fellow of Pembroke College, Oxford, and Emeritus Johnston Professor of Biochemistry in the University of Liverpool, died at Oxford on March 26 at the age of 79. Walter Ramsden, the son of Dr W H F Ramsden, of Saddleworth, went from Keble College, Oxford, where he distinguished himself in the honour school of physiology, to Guy's Hospital. He qualified in 1897 after three years as a Radcliffe Travelling Fellow, studying at Zurich and Vienna, and he proceeded D.M. in 1902. His election to a prize fellowship at Pembroke allowed him to devote himself to physiology and he became a university demonstrator and also taught physiology at Christ Church. In 1909 he served as senior proctor and became Johnston professor at Liverpool in 1914, and continued there until he reached the retiring age in 1931. He did some important work on the theory of emulsions, and was the author of several articles on this subject. He was a member of the Physiological Society and of the Biochemical Society.

(The Originators of Proteolysed Liver)

announce

HEPOVITE

A dry granular preparation of Malt and Enzyme Hydrolysed Protein rich in Natural Vitamins

COMPOSITION

Carbohydrate (Maltose) 33% Protein (N X 6.25) 50%
 (Supplying the amino acids Arginine Histidine Lysine Tryptophane
 Phenylalanine Methionine Threonine Leucine Isoleucine Valine
 and Cystine)

Each 30 grammes contains

Vitamin A	503 I.U.	Pantothenic Acid	11.3 mg
Vitamin D	50 I.U.	Pyridoxin	0.32 mg
Ascorbic	1.0 mg	Biotin	64.8 gamma
Riboflavin	2.0 mg	Folic Acid	150 gamma
Nicotinic Acid	6.5 mg	Inositol	8.1 mg

Choline Calcium Phosphorus and Iron are also present

USES To correct Nitrogen loss especially when this is due to faulty absorption to supply concurrently complete multiple natural vitamins

DOSE Sufficient to provide the required protein supplement (The palatability of Hepovite is such that most patients will readily take any recommended quantity either neat in milk or sprinkled on a wide range of foods)

SUPPLY Hepovite is not yet available for sale but limited supplies are available for clinical trial by hospitals and clinics

For promoting
*Natural
Restful
Sleep*

THE control of insomnia presents a problem that often cannot be effectively or safely solved by recourse to the use of hypnotic drugs

Ovaltine provides a safe and natural means of inducing sleep in many cases, especially where the basis of the insomnia is digestive unrest, nocturnal hunger, or nervous instability. Taken before retiring, it promotes quiet and restful sleep by reason of its gentle sedative effect on the nervous system and its faculty of assisting digestive ease.

Ovaltine is a natural food tonic prepared from milk, eggs and malt extract with a cocoa flavouring. It is possessed of a truly delightful taste and is appreciated by every type of patient.

SPENCER INDIVIDUALLY DESIGNED SPINAL SUPPORTS

Spencer Designers make positive support embodying comfort without undue weight

Patient with fixed kyphosis wearing a Spencer Spinal jacket designed especially for her

For spinal curvatures, injuries, or disease Spencer Designers create a spinal support that orthopaedic opinion finds most effective. It provides positive support with less weight and more comfort than does a brace.

The Spencer Spinal Support is designed to exert the degree of hyper-extension or flexion of the spine required by the surgeon for treatment of the condition in the individual patient.

Where immobilisation is needed, the necessary rigidity is incorporated.

Only if individually designed, cut made, and fitted for the one patient who is to wear it can a support be effective in the application of the necessary corrective and supportive forces on the body to aid reconstruction in the patient.

The Control of Scabies with **'TETMOSOL'**

brand

TETRAETHYLTHIURAM MONOSULPHIDE

'Tetmosol' is a powerful sarcopticide, and in the forms of 'Tetmosol' Soap and 'Tetmosol' Solution has proved highly effective in both the prophylaxis and treatment of scabies.

The Solution (25%), diluted with water before use, provides a most satisfactory and certain method of treatment. It produces a rapid cure of scabies and has the advantage that its application is painless and rarely gives rise to dermatitis.

'Tetmosol' Soap — a pleasantly perfumed soap tablet containing 5% tetraethylthiuram monosulphide — is primarily intended for prophylactic use against scabies. It has proved especially valuable for controlling outbreaks of the disease in families and in communities such as asylums, hospitals, schools, etc. The method of use is simple and convenient so that the co-operation of the scabies patient is readily secured.

'Tetmosol' Solution (25%) Bottles of 100 c.c., 250 c.c. and 2 litres. 'Tetmosol' Soap (5%) Single 3 oz. tablets and boxes of 36.

and had been secretary of the section of physiology at the annual meeting of the British Medical Association in 1904. After his retirement he returned to Pembroke College and still took a lively interest in college affairs. His biochemical work continued and he became particularly interested in the chemistry of silk proteins. He was one of the last men to hold an Oxford life fellowship.

GEOFFREY DUCKWORTH, M.R.C.P.

Dr Geoffrey Duckworth died suddenly at his home at Wimbledon Common on March 18 at the early age of 46. Educated at Rossall and University College, London, he entered St George's Hospital in 1926, and qualified in 1929. After serving a term of clinical assistantships he decided to take up dermatology as a specialty and obtained the M.R.C.P. in 1932. He was later appointed as skin physician to the Boleynbroke Hospital, Wandsworth Common, to St John's Hospital for Diseases of the Skin, and to the Royal Hospital and Home for Incurables, Putney. He was the author of a number of papers, among them a report on two cases of ariboflavinosis which appeared in the *British Medical Journal* in 1942.

A colleague writes: Geoffrey Duckworth will be remembered as a shy, diffident, scholarly doctor with an immense capacity for work and perseverance. He suffered from severe ill-health from his student days, and this culminated in his early death. With his fortunate financial background and happy family life he might well have taken a rather dilettante view of his profession, considering his delicate state of health. Duckworth, however, was not of this type. He gave of his best to his hospital patients and to the pursuit of learning in his chosen specialty. His untimely death will come as a great shock to his many friends.

Dr Leslie J. Harris writes: The Nutrition Society owes an immense debt to Sir JOSEPH BARCROFT for all the generous and unselfish work he did on its behalf. He had been active in the Society's interests ever since its foundation in 1941, and had been its chairman since 1945. No effort was too much for him in furthering its welfare, and the success of the Society has been the measure of his unstinted and unflinching devotion.

Dr WILLIAM JOHNSTON DEWAR died at his home in Arbroath on March 5 at the age of 76. Graduating M.B.C.M., with honours at Aberdeen in 1891, he took up general practice in Arbroath first in partnership with his father, the late Dr James A. Dewar, later on his own. He proceeded M.D. in 1905. After retiring in 1923 Dr Dewar devoted much of his time to public work. He was a member of the Arbroath Town Council for nine years.

Dr Vera D. Davidson writes: After he retired from practice Dr Dewar did not lose touch with his profession, being a constant welcome, and helpful visitor at Arbroath Infirmary where he observed with great interest every advance in treatment and equipment. His other interests were wide; his sympathies deep; he made himself always accessible to those in need of his advice or help. There must be many in his native town who can say that, turning in time of trouble to 'Dr Willie,' they have been assisted through their difficulties by his unstinted efforts on their behalf. He was a sincere member of the Episcopal Church in Scotland, and a practical friend to the children of Aberlour Orphanage. A gentle and whimsical humorist he was always the best of company and welcome wherever he went. His freshness of outlook he retained always and he never lost his sense of wonder. Sound physician, wise counsellor, and good friend Dr Dewar will long be missed.

Dr KENNETH ROBERT HAY, who died on March 12 in London, qualified in 1898. He came to St Bartholomew's Hospital from Caius College, Cambridge, and in due course became house physician to Sir Dyce Duckworth.

Col W. P. S. Branson writes: A tall spare habit of body and a face which in enemy hands had he ever had one—might have called too long until he smiled combined to give Kenneth Hay a serious air which belied the native gaiety of his spirit. Those who can revive the memory of their first visit to his lovely home Sacombe near Ware, will surely revive also their delighted surprise at finding in the grave young man they knew in London one who was in truth the chartered buffoon and laughter maker of his large and happy family at home. For such he was in those far off days. His health never of the most robust, led to his taking a voyage round the world at

about this time, followed by house appointments at the Metropolitan Hospital and at the East London Hospital for Children. A few may remember him at Shadwell, where he was casualty officer, and Dr Herbert Morley Fletcher, Sir Ernest Graham-Little, or Dr A. M. Gossage, who were assistant physicians at that time may recall the stentorian voice which could still the chatter even in that casualty department. He practised first in St James's Place and later in Mayfair, and was able to indulge an omnivorous taste in medicine, science, and the arts by use of the many facilities that lay to his hand in London. The Royal Society of Medicine, in whose historical section he held office at one time, the Royal Institution and meetings in many by-ways of knowledge, such as industrial psychology into which he loved to prowl wherever he could find them. During the first world war he served in the First London General Hospital at Camberwell, and gained the O.B.E. For some years between the wars he supervised the health of the staff of the Army and Navy Stores. But a great part of his time went in the care of his many friends, while he fought off with disdainful courage a life long susceptibility to the fogs of his beloved London. The second world war found him still busy with tribunals of various sorts and with medical services to wartime industry, and even after it he remained in harness to the end as he would have wished.

Dr WILLIAM SALISBURY-SHARPE died in his sleep on March 15 at the age of 83. He qualified from St Mary's Hospital in 1888, proceeded M.D. in 1903 and took the F.R.C.S. in 1909. He had been medical officer to the G.W.R. men's club and later became chief consulting surgeon to the G.W.R. He was also physician to the Mildmay Mission Hospital in Bethnal Green and assistant surgeon to the Central London Ear and Throat Hospital, as it was then called. A member of the old Volunteer Corps, he later joined the Territorials and gained the rank of lieutenant-colonel and the T.D. He took his field ambulance to France in 1914 and then to Salonika. After the war while carrying on a West End practice he obtained the M.R.C.P. London, and the D.T.M.&H. a remarkable achievement for a man approaching 60. On retirement he settled in Lincolnshire, which was his native county. He was county commissioner for the Red Cross in Lincolnshire and had been D.C.M.S. for the London region. He was a fine horseman and a good shot and in appearance and bearing might easily have been mistaken for a regular soldier. His funeral took place at Mavis Enderby, where he was born and where his wife was buried. He leaves two daughters and a son a colonel in the R.A.M.C. at present serving in the Middle East.

Dr ROBERT GEORGE BANNERMAN died in London on March 26 at the age of 56 after a short illness. A student of Edinburgh University and London Hospital he graduated in 1914, proceeding M.D. in 1919. During the 1914-18 war Dr Bannerman was in charge of the Dyke Bar War Hospital and later of the Roy Broyston War Hospital. He was later appointed to the staff of the British Hospital at Montana Switzerland. Returning to England he worked at the Treloar Cripples' Home in Sussex before being appointed pathologist to the Inverness Memorial Hospital. He had been a member of the British Medical Association for twenty years and was also a member of the Association of Clinical Pathologists. During the recent war he served for a short time in the R.A.M.C., but had to relinquish his commission on account of ill-health.

A colleague writes: R.G.B. was a shy man who eschewed publicity and ambition—yet he could look back on an active past which had made substantial contribution to the science of pathology, notably in haematology. He had a gentle touch and warm sympathy with those who were afflicted; he was a cultured man with sincere appreciation of literature and music and a humorous teller of choice academic stories dating back to his Edinburgh days. His memory will be cherished by many a colleague and friend.

Dr WILLIAM ARCHIBALD who died recently at Strone, Argyll shire graduated at Glasgow in 1901. He took the Cambridge D.P.H. in 1905 and proceeded M.D. in 1906. He was the first whole time medical officer to the Borough of Luton and was appointed in 1908 at a salary of £400 a year. The local government board advised that the salary offered should be £500 a year, and gave only a conditional approval of the appointment until such time as their recommendation was accepted. Dr Archibald was medical officer of health at Luton until April 1937 when he retired a little in advance of the usual age because of ill health. He witnessed the consolidation of tripartite health services and the development of personal health services in a borough which had a population of some 40,000 when he assumed office and which had grown to over 80,000 when he retired. He was interested in epidemiological

An Imperial Cancer Research Fund Lecture will be delivered at the College (Lincoln's Inn Fields, WC) by Dr James CRAIGIE F.R.S. on Wednesday, April 16 at 3.30 p.m. His subject is 'Relationship of Virus and Host-cell with Reference to Latent and Cryptic Infections'. The lecture is open to medical practitioners, scientists and advanced students.

Medical Notes in Parliament

The Penicillin Bill was taken in Committee by the House of Lords on March 25. On Clause 1, which controls the sale and supply of the substances to which the Bill applies, LORD MARLEY moved an addition to subsection 2 (d). This subsection authorizes the sale or supply of these substances to any authority or person carrying on a hospital clinic nursing home, or other institution providing medical, surgical, dental, or veterinary treatment. LORD MARLEY proposed to add after treatment 'the words "under the direction of a duly qualified medical practitioner, a registered dental practitioner, or a registered veterinary surgeon, or a person acting in accordance with the directions of any such practitioner or surgeon"'. He said the gap in paragraph (d) caused anxiety among qualified medical officers.

Replying for the Government, LORD LISTOWEL said institutions obtaining a supply of penicillin could not, under subsection 1 (a) of the same Clause, use it for treatment except in accordance with the directions of a qualified practitioner. LORD MARLEY said this was unsatisfactory but he withdrew his amendment and the Bill passed through Committee without alteration.

Curtis Report Recommendations

Mr ATTLEE announced on March 24 the acceptance by the Government of the recommendations of the Curtis and Clyde Committees that the task of providing a home background for children deprived of a normal home life should be brought under the supervision of a single central department. It had decided that for England and Wales, this central jurisdiction should be concentrated in the Home Office. A new and enlarged Children's Branch would be created in the Home Office with an expanded inspectorate organized on a regional basis. The primary function of this Branch would be to ensure that everything possible is done to give to homeless children not only the material care but also the sense of security and status which a normal home provides. A standing advisory committee widely representative of the many interests involved and including representatives of the Ministry of Education, the Ministry of Health and the Ministry of Labour would be appointed to assist the Home Office in its administration. In Scotland the Secretary of State proposed to assign to the Scottish Home Department functions broadly similar to those which would be given to the Children's Branch of the Home Office and to appoint a Scottish standing advisory committee. The existing special responsibilities of the Admiralty and the War Office for orphans of Service men and of the Ministry of Pensions for war orphans would continue. The Government accepted the recommendation that county councils and county borough councils in England and Wales and county councils and town councils of large burghs in Scotland should be the local authorities responsible for the welfare of all children deprived of a normal home life.

National Service Bill

Moving on March 31 the Second Reading of the National Service Bill, Mr GEORGE ISAACS explained that in normal circumstances doctors and dentists would find themselves called up round about the age of 25 but there would be many in the field of call up taking specialist courses and wanting to become specialists in one branch of their profession. When an individual requested that it should be done his call-up could be postponed and he would be liable to be called up up to the age of 29. That had been done, Mr Isaacs said to meet the needs of the professions so that men would get their additional training. At the same time it was an advantage to the Services because they would have within their ranks men with higher qualifications to assist in the professional work of the doctors and dentists in the Forces.

Mr RHYS DAVIES moved the rejection of the Bill. The debate continued on April 1, when the Second Reading was carried by 386 to 85.

Paper for Periodicals—On March 27 Mr PICKTHORN inquired why periodicals had recently been limited to 35% of their pre-war paper consumption and whether paper mills had been and were being supplied with enough coal to meet this demand. Sir STAFFORD Cripps said that owing to the shortage of coal it had been necessary to reduce the amount of paper to be licensed for periodicals. In many cases even the reduced amount of paper might not be available. The publishers had been warned of this.

Medical News

Dr J. Purdon Martin, F.R.C.P., will deliver the Lumleian Lectures before the Royal College of Physicians of London (Hall Mall East S.W.) on Tuesday, April 15, and Thursday, April 17, at 5 p.m. His subject is 'Consciousness and its Disturbances considered from the Neurological Aspect'.

The first Sir Julius Wernher Memorial Lecture of the Institution of Mining and Metallurgy on "The History and Prevention of Silicosis, with Special Reference to the Witwatersrand" will be given by Major-Gen. A. J. Orenstein, M.D., F.R.C.P., chief medical officer, Central Mining—Rand Mines, Ltd., at the Royal Institution, 21, Albemarle Street, London, W., on Tuesday, April 15, at 5 p.m. Admission to the Lecture is free, without ticket.

A conference on "Silicosis, Pneumoconiosis, and Dust Suppression in Mines," arranged jointly by the Institution of Mining Engineers and the Institution of Mining and Metallurgy, will be held at the Royal Institution, 21, Albemarle Street, London, W., on Wednesday and Thursday, April 16 and 17, and will be opened by the Minister of Fuel and Power. The programme is as follows: April 16, 10.30 a.m., opening address by the Minister of Fuel and Power. Papers on 'The Pathology of Silicosis,' by Dr A. Sutherland Strachan, 'The Pneumoconiosis of South Wales Coal Workers,' by Dr J. Gough, 'Some Aspects of the Pathology of Pneumoconiosis. Part I—The Mechanism of the Removal of Dust Particles from the Lung,' by Dr A. Polcard, Associate Member of Académie des Sciences and Académie de Médecine de France.

Some Aspects of the Pathology of Pneumoconiosis," by Dr A. Polcard. 2.30 p.m., Pneumoconiosis on the Kolar Gold Field, by Dr A. Caplan and Mr D. J. Burdon. 'The Control of Silicosis in the Haemite Mines of the North West of England,' by Dr John Crow, 'A Review of the Work of the Silicosis Medical Bureau Johannesburg,' by Dr J. M. Smith, 'Aluminium Therapy and Prophylaxis for Silicosis,' by Dr Peter W. Edwards, a paper on the treatment and prevention of silicosis in the mines of Western Australia (not yet received). April 17, 10.30 a.m., 'Development of Silicosis Suppression Methods on the Witwatersrand—Ventilation and Dust Suppression,' by Mr J. P. Rees, 'Dust Suppression in Great Britain,' by Mr J. Ivon Graham and Dr T. David Jones. 'The Government Miners' Training Schools (incorporated in the Union of South Africa)—an Outline of Two Vocational Training Schemes,' by Mr E. J. Bolitho, 'The Organization of Dust Research in South Wales,' by Dr T. David Jones, Film, 'Dust Suppression in South Wales Coal Mines,' 2.30 p.m., 'Dust-Sampling and Control,' by Mr J. P. Rees, 'The Sampling of Airborne Mine Dusts,' by Dr D. G. Skinner, Dr A. G. Withers, Dr J. H. Griffiths and Mr F. T. Williams, 'The Examination of Airborne Dust in Coal Mines for the Evaluation of the Possible Health Hazard,' by Dr D. G. Skinner and Dr J. H. Griffiths, 'Types of Rock Encountered in Mining on the Witwatersrand and their Mineral Constitution,' by Dr R. J. Bridges. Admission to the conference is free, but applications to attend must be made on the prescribed form obtainable from the secretary of either institution at Salisbury House, Finsbury Circus, London, E.C.2.

A meeting of the Middlesex County Medical Society will be held at West Middlesex County Hospital, Isleworth on Tuesday, April 15, at 3.30 p.m., when Mr R. L. Galloway will speak on "Peptic Ulceration" and Dr M. M. Deane will show a colour film on "Partial Gastrectomy."

A general meeting of the Chelsea Clinical Society will be held at South Kensington Hotel, 41, Queens Gate Terrace S.W., on Tuesday, April 15, at 6.30 p.m. for 7 p.m., when Mr Duncan C. L. Fitzwilliams will read a paper on "Sir Thomas More and Utopia."

The annual meeting of the Society for the Study of Addiction will be held at the Medical Society of London, 11, Chandos Street W., on Tuesday, April 15, at 4 p.m., when there will be a symposium on "The Uses of Amphetamine (Benzedrine)," to which Dr W. R. Bett, Dr H. Crichton Miller, Dr J. D. N. Hill, Dr H. Pullar-Strecker, Dr H. J. Shorvon, Dr J. Yerbury Dent, Prof. R. C. Browne, and Dr G. R. A. de M. Rudolf will contribute.

The Sylvanus Thompson Memorial Lecture will be delivered before the British Institute of Radiology (32, Welbeck Street, London, W.) on Thursday, April 17, at 8 p.m., by Prof. R. Sievert on "Dangers and Protection in Radiological Work."

The Third International Congress of Catholic Doctors will be held at Lisbon from June 17 to 23. Arrangements are being made for a party from this country to take part. Any Catholic doctor wishing to join the party will be welcome and should communicate as soon as possible with Dr W. J. O'Donovan, O.B.E., 130, Harley Street, W.1 (Tel. Welbeck 3349).

EPIDEMIOLOGICAL NOTES

More Smallpox Cases

During the past week smallpox has been diagnosed at Scunthorpe Borough, Lincs., and at Doncaster County Borough, Yorks., under circumstances suggesting association with the recent outbreak at Grimsby County Borough (*Journal* March 8, p. 320, and March 15, p. 362). At Bilston Borough, Staffs., the importation of smallpox from India is suspected. At Stepney London one secondary case infected in Mile End Hospital was removed on March 21. Since then there have been no further notifications.

The Scunthorpe Borough case is an unvaccinated platelayer, 35 years old resident in a common lodging house 2 Manley Street, Scunthorpe. He developed a rash on March 22 and was removed to an infectious diseases hospital on March 25, diagnosed as a case of chickenpox. On April 1 laboratory examination suggested smallpox, which was confirmed clinically on the following day. Contacts not recently vaccinated are numerous and secondary cases are already due to crop. One has been removed on suspicion. Two men who left Grimsby while under surveillance as contacts stayed at the common lodging-house at Scunthorpe at a material time. It is not improbable that other unidentified and itinerant contacts have moved on to other common lodging-houses, and special vigilance is indicated.

In Doncaster County Borough an assistant master at a preparatory school vaccinated thirteen years previously, developed a rash on March 27 and was removed to Doncaster Smallpox Hospital on March 31. Modified smallpox has been confirmed. Fortunately this patient was confined to his residence from the date of appearance of the rash and is unlikely to have infected his pupils, who must, nevertheless, be under surveillance. The source of infection is unknown, but a link with Grimsby, through another contact there, is suspected.

The Bilston Borough case is that of a soldier vaccinated in infancy, in 1944 and in 1946. He travelled from Agra to Karachi by train and thence by air via Cairo and Marseilles to Heath Row. He reached Bilston on Feb. 23 and developed fever on March 2 and a few spots on March 5. Subsequently his mother vaccinated in infancy, became ill on March 19 and developed a rash. Another unvaccinated contact sickened on March 23 and developed a rash two days later. Initially chickenpox was diagnosed, but variola virus has been cultured and there is now strong suspicion of smallpox. The rashes reported to be superficial and centripetal, have obviously given rise to considerable difficulty in diagnosis.

Discussion of Table

In *England and Wales* the notifications of infectious diseases showed only small changes. There were decreases in the incidence of whooping cough 130, acute pneumonia 41 and dysentery 25, and increases in the returns of diphtheria 28, scarlet fever 26, and measles 26.

A small decrease in the notifications of whooping cough was shown in most areas, the only exception was Yorkshire, where the incidence remained practically unchanged. Yorkshire West Riding, with an increase of 43 in the returns for acute pneumonia, was the only exception to the general decline.

The largest change in the notifications of scarlet fever was a decrease of 28 in London. The rise in the incidence of diphtheria was contributed by three counties: Lancashire 12, London 11, and Glamorganshire 11. The largest rises in the notifications of measles were Leicestershire 164, Yorkshire West Riding 159, and Southampton 113. The largest falls were Lancashire 188, Cheshire 128, and Durham 90.

There were 13 cases of dysentery in Lancashire. Notifications of cerebrospinal fever were 7 above last week's total, which was the highest level for just over four years.

In *Scotland* the only variations in the notifications of infectious diseases were decreases in scarlet fever 37 and whooping-cough 30. A fall of 8 cases in the notifications of diphtheria was recorded in Glasgow.

In *Eire* the chief feature of the returns was a decrease of 110 in cases of whooping cough. No further cases of whooping cough were reported from the outbreak in Tipperary.

In *Northern Ireland* the outbreak of measles in Belfast C.B. continued to decline and only 58 cases were notified during the week.

Week Ending March 29

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,317, whooping cough 2,263, diphtheria 254, measles 10,780, acute pneumonia 1,025, cerebrospinal fever 115, dysentery 85, smallpox 1.

INFECTIOUS DISEASES AND VITAL STATISTICS

No 12

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) *England and Wales* (London included) (b) *London* (administrative county) (c) *Scotland* (d) *Eire* (e) *Northern Ireland*.

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in *England and Wales* (including *London*), (b) *London* (administrative county) (c) The 16 principal towns in *Scotland* (d) The 13 principal towns in *Eire* (e) The 10 principal towns in *Northern Ireland*.

A dash — denotes no cases. A blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	114	10	33	11	—	67	5	58	1	1

Whooping-cough Deaths	2 277	230	354	83	12	2 190	192	122	45	4
Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	574	75	89	—	21	478	69	73	35	14
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	6,773	1100	846	186	6 197	972	846	257	16	—
Live births Annual rate per 1 000 persons living	10 583	1627	1387	329	8 198	1199	1024	346	27	—
Stillbirths Rate per 1 000 total births (including stillborn)	272	28	42	—	245	32	42	39	—	—

* Measles and whooping-cough are not notifiable in *Scotland* and the returns are therefore an approximation only.

† Includes primary form for *England and Wales* *London* (administrative county) and *Northern Ireland*.

‡ Includes puerperal fever for *England and Wales* and *Eire*. Return of births and deaths for *Eire* for weeks ended March 8, 15 and 22 is not yet available.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Consanguineous Marriage

Q—What are the medical disadvantages of marriage between first cousins? The couple in question are very much in love.

A—One of the inescapable risks inherent in any marriage is that both partners may happen to carry the same harmful recessive gene. If they do the chance is one in four that any child will receive one from each parent and so be affected. In this way, often like a bolt from the blue, one, two, or more children in a sibship will be albinos or deaf-mutes, or will develop amaurotic idiocy or retinitis pigmentosa. In any given random marriage the risk is a small one, because such genes are rare and both partners will seldom carry the identical one. Blood relatives however, share more of the same genes than do unrelated people, having, of course, received them from the same source. Actually, if a man carries a particular recessive gene, the chance is one in eight that a first cousin will also carry it. Thus the risk of a recessive defect appearing in the children is greater in a cousin marriage than in an unrelated alliance. But though relatively the risk is considerably increased, it still remains a small one absolutely, if there is no contraindication in the family history the risk is not of such an order that a wise couple knowing all the facts might be expected to decline. This particular couple might well feel that their affection for each other more than outweighs one relatively small additional risk in a project filled with risks both genetic and non genetic.

If however there is any history of the appearance of a recessive abnormality in either family, careful scrutiny of the family history would be necessary. Furthermore, in view of its presumed recessive mode of transmission, schizophrenia in either family would call for detailed investigation, this proviso might also be extended to definite schizoid personality. For a further discussion of the problems raised by cousin marriage see Roberts, *An Introduction to Medical Genetics* Oxford University Press 1940 (especially pp 63-70).

Fluorescent Fungi

Q—What ringworm fungi fluoresce under Wood's light? Are such fungi identified according to their fluorescence under ultra violet rays of known Angstrom units? If so what species react to light waves of 3650 Å and 4200 Å? References to work on this subject would be appreciated.

A—In the clinical field the microspora (human and animal) affecting hair fluoresce a bright greenish-yellow under Wood's light which emits rays of 3650 Å. Favus gives a similar but less brilliant fluorescence and endothrix infection a dull bluish grey colour. Tinea versicolor appears golden-yellow under Wood's light. Cultures of fungi can within certain limits be identified according to their fluorescence, and this applies to the trichophytia as well as to those fungi mentioned above. Reference should be made to the *Introduction to Medical Mycology* by G. M. Lewis and Mary Hopper (1943, Year Book Publications, Chicago), where the subject is fully discussed.

Cement Dust

Q—Is there any danger to health from cement dust (1) to the workers in the factory (2) to the people living in the vicinity?

A—A survey of seventeen cement plants supported previously held views that in comparison with the dust hazards from silica the problem in the cement industry is trivial. Prolonged inhalation of dust from finished cement produces such slight reaction that little or no abnormality is seen in the radiograph. In the group of 2278 surveyed the evidence of tuberculosis and other chronic infections of the lungs was less than that in the general population. Cement dust may cause con-

junctivitis, slight catarrhal changes in the mucous membrane of the nose and upper air passages, and dermatitis. The effect of cement dust on people living in the vicinity of cement factories has not been the subject of medical research although mention has been made (Standley, *Journal* March 18 1944 p 412) of irritation of the eyes from falling particles. Methods of preventing or lessening the emission of dust from cement factories involve highly technical and specialized engineering questions, on which *Industrial Dust* by P. Drinker and T. Hatch (McGraw Hill, London 1936) may be consulted.

Cider and Rheumatism

Q—Are there any grounds for the current belief that cider drinkers do not suffer from rheumatism of the arthritic type? Does cider contain a large quantity of vitamin and yeast products which might be beneficial?

A—There are no grounds for the belief that cider drinkers do not suffer from the arthritic type of rheumatism. Cider does not contain a high quantity of vitamin or yeast products. Salicylic acid is often added to cider, sometimes in very large amount, and this may be the origin of the idea. It is obvious that the value of salicylic acid for acute rheumatic fever does not justify the conclusion that cider drinkers will be protected from rheumatoid arthritis because the cider contains salicylic acid.

Nervous Exhaustion

Q—What is meant by 'nervous exhaustion'? Is there such a clinical entity? How may the condition be estimated and what treatment is advised?

A—The term 'nervous exhaustion' usually refers to a condition of psychological origin, due to such causes as lack of incentive, strain, overwork, and an incapacity to cope with the problems of life, or to the fact that the patient, owing to earlier experiences, is making too great a demand on himself with a consequent reaction in the opposite direction, and a subconscious refusal (though coupled with a conscious desire) to continue to make the effort. One often finds this conflict in those who were invalids as infants or premature babies, or lacked affection, so that life was a perpetual effort and strain and this becomes a vicious habit even when the need for such effort has passed. The futile struggle ultimately breaks them down. But exhaustion, of course, accompanies vitamin deficiency of all kinds, as well as other biochemical disorders perhaps as yet unascertained and it is not always easy to exclude the physiological factor. That a physiological factor cannot be found does not mean that it is not present. The term 'nervous exhaustion' may generally be used of the biological failure or incapacity of the organism to face the demands of life, from whatever cause, combined with lack of incentive and therefore lack of production and liberation of energy to meet those demands. Aetiologicaly we may distinguish between those conditions where for physiological reasons the individual is lacking in energy, and therefore incapable of meeting the demands of life, and those conditions in which there is lack of incentive in life, and therefore the necessary energy is not forthcoming. The lack of energy is in one case the cause and in the other the effect but the symptoms are not unlike.

High Diastolic Pressure

Q—Patients who appear to be perfectly fit and able to do heavy work are often found to have an abnormally high diastolic pressure and continue in this state for years. For example one sometimes encounters a healthy muscular man aged 40 or so with a blood pressure of 140/110 who has tachycardia and has had it for years. Such patients are often of the sympathetotonic type and seem able to vary the pulse rate at will. What are the significance as regards prognosis and the probable cause?

A—The systolic blood pressure is a measure of the pumping capacity of the left ventricle, whereas the diastolic pressure indicates the resistance against which it has to work. The higher the diastolic pressure the more work will the left ventricle have to perform to maintain an efficient circulation. A patient with a true diastolic pressure of 110 mm. and a well-compensated heart usually has a systolic pressure of over

170 mm, and only when failure sets in does the systolic pressure fall. In a healthy, muscular man with an apparent blood pressure of 140/110 this diastolic reading probably does not represent the true diastolic pressure. Errors may arise because compression of the arm in some subjects, particularly those of the sympatheticotonic type, causes reflex vasomotor spasm, so giving a false reading, or because the diastolic pressure is lower than it appears. It must be remembered that clinical methods of measuring blood pressure are rough and considerable margin for experimental error must be allowed, and the readings should be assessed in conjunction with the whole clinical picture.

Small Stature

Q—*Can you suggest treatment for an undersized patient of 9½ years, weight 49 lb (22.2 kg) and well proportioned. He seems otherwise normal. The mother is above average height, the father average, but there are some rather diminutive aunts. Is the pituitary growth hormone which has been tried successfully in California commercially available?*

A—The patient's small stature appears to be determined genetically, in view of the family history, but the mechanism is nevertheless through a deficiency of pituitary growth hormone. The condition is comparable to that of strains of dwarfed mice, which respond both to pituitary growth hormone and, to a less extent, to thyroid gland. The combined treatment is sometimes, but not invariably, successful in undersized children. There are two forms of pituitary growth hormone available in this country, but supplies are intermittent. The dosage is 5 ml intramuscularly twice weekly, or, if practicable, 1 ml daily or 3 ml three times a week. The treatment should be continued for six-weekly periods, with an interval of six weeks to allow the antibodies that form to disappear from the blood. The thyroid could be given in 1-gr (65 mg) doses daily, and continued without intermission, provided the pulse rate is not unduly accelerated.

Diuretic Treatment of Adiposity

Q—*Patients given urea crystals for obesity have not reported the diuretic effect anticipated. What is the rationale of giving urea in these cases and has it any advantage over thyroid treatment? I take it that urea would be contraindicated in persons with signs of kidney disease but is there any other associated danger?*

A—Urea is given for its diuretic effect, the extra water being lost in an attempt to excrete the heavy doses of urea and keep the blood urea at normal levels. An alternative is ammonium chloride in 7½-gr (0.5 g) enteric-coated tablets, 1 tablet thrice daily after food, or injections of a mercurial diuretic such as mersalyl. The diuretic treatment of adiposity is based on the fact that on limited diet obese patients lose weight for a while and then stop, and the effect of diuretics shows that this refractory stage is due to a retention of fluid. It is also postulated that normal adiposity is associated, at least in some cases, with retention of fluid, and many fat patients put on weight before menstruation and lose it after the period, the phenomenon being believed to be due to water retention. There is no real comparison between urea and thyroid because the chief action of the latter is to increase metabolism. Thyroid gland has, however, no specific effect on fat, and tends to catabolize protein at the same time as, or even before, fat. It is therefore of limited value in the treatment of adiposity. Urea is contraindicated in patients with renal insufficiency but apart from this it cannot be regarded as a dangerous form of therapy.

Port-wine Naevus

Q—*What is the prospect for a child of 2 with a port-wine naevus over about half her face? She is being treated with thorium X and has had four applications over a period of eighteen months. Is there any treatment other than thorium, likely to succeed without leaving disfigurement?*

A—Grenz-ray therapy (1400 r units repeated at intervals of six months on three or four occasions) is more effective than thorium X. Plastic surgery may be considered, but if some fading is achieved by the Grenz-ray therapy such disfigurement as remains may be concealed by the application of certain special cosmetic preparations.

Letters and Notes

A Method of Giving Penicillin

Dr R M DOWDESWELL (Nairobi) writes: My attention was drawn to Dr M Machado Espinosa's letter (Feb 1, p 197) on "A Method of Giving Penicillin". The method is very similar to one which I described in a paper published in the *East African Medical Journal* 1946, 23, 139, and in a note in the same journal, 1946, 23, 181. Since the publication of these trials the method described has been used in various hospitals and dispensaries in this Colony. At the Infectious Diseases Hospital, Nairobi, 1,121 cases of acute gonorrhoea have been treated during the last nine months using this technique of one injection of 150,000 units with blood with 13 failures, which responded to a second similar injection.

Last Scarce Substances Order Revoked

The Scarce Substances Order, 1946, No 490, which confirmed and established authorized alternatives for liquid extract of ipecacuanha and for tincture of ipecacuanha was revoked on March 1, 1947. This means that whenever liquid extract of ipecacuanha or tincture of ipecacuanha is ordered on a prescription it must be dispensed. This revocation ends all the Scarce Substances Orders made by the Ministry of Health during the war.

Pseudo hermaphrodite

Mr R OGIER WARD (London, W) writes: With reference to the case of the pseudo hermaphrodite described in "Any Questions" (March 8, p 322) and the advice given that if the sex remained in doubt the child should be brought up as a male and ultimately be sent to a boys' school, an African student in Uganda was pressed by the examiner in forensic medicine as to how to decide the sex in such cases, "for, you see, some day the child will have to go to school". After some thought the student replied, "Sir, I send it to a mixed school".

Shortage of Nurses

SERO MELIORA writes: My daughter, who is a S.R.N., has just returned to the metropolis to a midwifery training centre to do the district work for her S.C.M. She writes: "We are in the next-door house—three of us in one room on the ground floor. Sanitaries consists of a 'pot' as we are not supposed to use the lavatory in the house. The problem is emptying it—so we use the lavatory. Washing is next door." On arrival (after a journey seriously delayed by the weather and without food) her supper, at 9.30 p.m., consisted of beans, toast, and tea, which she had to reheat. She is not complaining—merely stating facts. I regret that I cannot have my name published with this letter—victimization is not unknown.

Sodium Morrhuate Injections

Mr G H COLT (London, W) writes: My acquaintance with the literature of varicose vein injection is not as complete as it was ten years ago. The sudden dangerous symptoms and signs of onset are generally attributed to anaphylaxis. I venture to think they may easily be due to fat embolism. The injection of air into the blood stream, even slowly, is asking for trouble. G. A. Clark pointed out many years ago (I have not got the reference now) that fat embolism was frequently missed post mortem. An authoritative summary in such cases would be of great value. Tests with facilities for animal experiment could easily settle some of the points.

Correction

In our report of Sir Andrew Davidson's speech at the Council of Social Service Conference (*Journal* March 15, p 346) the word "pulmonary" in the third line of the second paragraph should read "non-pulmonary".

LONDON SATURDAY APRIL 19 1947

LOUIS PASTEUR*

BY

Sir ALEXANDER FLEMING, FRS, FRCP, FRCS

I feel that it is a very great honour to have been asked to deliver this lecture on Pasteur, but I accepted the invitation with great trepidation, for I felt that I should be unable to do justice to so memorable a subject. We are grateful to M. Leveille for coming to London and setting up this Pasteur exhibition. I saw it in Paris and was struck then with its comprehensiveness and arrangement. But M. Leveille knows that the genius of Louis Pasteur is revered in Britain as it is in France.

Louis Pasteur was just a citizen of France—not an ordinary citizen, as it turned out, and there was nothing in his origin to indicate that when he died—and 50 years after his death—he would be a national hero. His great grandfather, grandfather, and his father were tanners. Perhaps had circumstances been different one of these ancestors might have become famous, but son followed father in an essential occupation. Pasteur's father, who on the battlefield had been decorated with the Legion of Honour, appreciated the advantages of education, and Louis, instead of becoming a tanner, was admitted to the Ecole Normale in Paris, where he seized with avidity the chances of learning, particularly chemistry and physics, under the distinguished teachers of that institution. He obtained his degree, but even then there was no real indication of his coming fame.

Louis Pasteur in his youth and throughout his life believed in hard work. He lived for his work and put his whole heart and soul into it. His was not a 40-hour week. He worked so constantly in his laboratory that it was inevitable that he became a beautiful technician, and throughout his life he had no use for sloppily performed or ill-conceived experiments. His first momentous discovery was the dissymmetry of crystals. Like many others, he had been puzzled by the difference between tartaric and racemic (or paratartaric) acids. These two chemicals appeared to be identical in every way except that, whereas racemic acid solutions had no influence on polarized light, tartaric solutions rotated this to the right. When Pasteur examined the crystals of a salt of racemic acid with the microscope he noticed that the crystals were not quite identical and could be divided into two groups. In one of these groups a particular facet was on the right side while the other group had the same facet on the left. They were in fact mirror images of each other and might thus be compared with a pair of gloves. Pasteur had vision, and with extraordinary care and perseverance he separated his right- and left-handed crystals into distinct groups.

Then he made solutions of these and tested them on the polariscope. The solution of the right-handed crystals deviated the polarized light to the right, the left-handed crystals to the left, and when the solutions were mixed in equal proportions there was no deviation—it was back at the indifferent racemic acid.

A New Science

Pasteur had solved a mystery that had puzzled older and more famous chemists. Little wonder is it that he was excited and rushed out and kissed an attendant whom he met outside the laboratory door. You can imagine the feelings of young Louis Pasteur when later he visited the great Biot to demonstrate his discovery. Biot, like a careful scientist, took no risks. Pasteur was given tartaric acid and the chemicals necessary for its crystallization. He made the solutions, which Biot kept in a cupboard till the crystals had formed. Pasteur separated his right- and left-handed crystals and Biot tested them in the polariscope. It was as Pasteur had said, and we can honour Biot for his immediate remark: "My dear boy, I have so loved science all my life that this makes my heart beat." From that day Biot was Louis Pasteur's friend and helper.

But he was not to stay in Paris uninterrupted. He was sent to Dijon and later to Strasbourg as a teacher. In Strasbourg, possibly the most important thing he did was to marry Mademoiselle Laurent, the daughter of his chief. She proved a mainstay throughout his life, and well deserved the tribute of one of Pasteur's disciples: "She was not only an incomparable companion for her husband but also his best collaborator." He pursued his studies in crystallography and he pursued racemic acid. No one knew how to make it. He heard of people in Leipzig and Vienna who were supposed to be able to do so, and off he dashed. But in the end he had to make it himself, and this gained for him the ribbon of the Legion of Honour and a prize of 1,500 francs from the Pharmaceutical Society of Paris.

In another pretty piece of work which he did later he used a common blue mould, a penicillium. When this was grown on racemic acid it assimilated the right-handed portion leaving only left-handed tartaric acid. A remarkable example of the extraordinary power of selection of a living organism. People may say and did say: "What is the use of all this? Why such a fuss about a little dissymmetry of crystals?" You can answer like Franklin: "What is the use of a newborn child?" Pasteur's first scientific baby, born of tartaric acid, inspired later workers so that a complete new science of stereo-chemistry has arisen explaining structure and enabling synthesis of many organic compounds. In London this work did not pass

* A lecture delivered at the Science Museum on April 10 to inaugurate the Pasteur Exhibition, temporarily transferred to London from the Palais de la Découverte in Paris.

170 mm, and

fall But notice, for it earned for him the Rumford Medal of the Royal Society—and that at 34 years of age

In 1854 Fate ordained that Pasteur should be sent as Dean of the Faculty of Science to Lille One of the industries of Lille was the production of alcohol by fermentation of beetroot In those days the prevalent theory of fermentation was that of Liebig—that it was a purely chemical process in which yeast played no active part Pouchet and Schwann had produced good evidence that it was a living organism, but Liebig and his supporters would not have it that a living yeast took any part in the fermentation process

The father of one of Pasteur's students was worried by the irregularities of his fermentations and asked Pasteur to help him This was the stimulus that set him off on his study of fermentations, which occupied him for many years and led him on to his later work on animal infections He set to work with his microscope and found that in the unhealthy lactic fermentations the globules were elongated and quite unlike the rounded globules of yeast found in the healthy alcoholic fermentations Some of the products of these fermentations were optically active His previous work had convinced him that this optical activity was a property possessed by substances synthesized by living things, in contradistinction to substances synthesized chemically in the laboratory He was therefore predisposed to consider these ferments as living organisms In the fermentation of impure substances like grape juice and beer wort there were many complicating factors, so he prepared a culture fluid containing only a watery solution of sugar, mineral phosphate, and an ammonium salt No organic nitrogenous matter was present In this simple medium a minute implantation of yeast promptly fermented the sugar, thus confounding the upholders of the purely chemical theory of fermentation, who had maintained that without organic nitrogenous material such fermentation was impossible Perhaps more important for us in this was the fact that Pasteur initiated the method of working with a simple culture medium in which the chemical changes could be more readily observed This was an enormous advance and is the method still used by the bacteriological chemists Thus even in his early work on lactic fermentation he was laying the foundations of bacterial culture

It is quite impossible to go into details of this work here It received much criticism, but Pasteur was a fighter as well as a wonderful experimenter and he was able to confound his critics He had got to the stage when he wrote

I can bear witness to the existence of a large number of distinct yeasts setting up chemical transformations in accordance with their nature and constitution, but most frequently the nourishment suited to one allows others to develop Hence arise most complicated phenomena liable to constant variations If one does succeed in separating one of these ferments and making it grow by itself, it produces the corresponding chemical change with remarkable precision and simplicity

That is as true to-day as when he wrote it

Having got so far with these fermentations, and having shown that they were due to living organisms, the next question was, Where did these ferments come from? Did they arise spontaneously or did they come from outside? The question of spontaneous generation had been discussed for centuries Many and curious were the prescriptions for producing animals Virgil's method for producing bees was

'Kill an ox two years of age, whose young horns are just beginning to curl on his brow place him in a narrow enclosure strewn with leaves of thyme and rosemary freshly gathered, and soon from his fermenting humours there rises a swarm which fills the air like rain from summer clouds'

Van Helmont had a recipe for producing rats

Cork up a pot containing corn with a dirty shirt, let about 21 days a ferment coming from the dirty shirt combine with the effluvium from the wheat the grains of which are turned into rats, not minute and puny, but vigorous and full of activity

This sounds almost as learned as some of the explanations of things which we hear to day and possibly is as truthful

In the 18th century Spallanzani had produced experimental evidence that spontaneous generation did not exist but people were not convinced, and the controversy went on In 1859 the academy offered a prize for "an endeavour by means of careful experiments to throw new light on the question of spontaneous generation" Pasteur's studies on fermentation fitted him for this new investigation His seniors, Biot and Dumas, tried to dissuade him, but he went on

We have not time to go into the multitude of experiments which Pasteur made on this subject or into his controversy with Pouchet or Bastian, but one simple experiment must be mentioned The neck of a flask half filled with a fermentable fluid was drawn out in a swan's neck form The fluid was boiled to sterilize it, and then the flask was allowed to stand at a temperature suitable for fermentation No fermentation occurred, although it promptly appeared in a similar flask in which the neck had not been drawn out The dust dropping from the air settled on the bend of the drawn-out flask and never reached the fluid, but if the flask was tilted so that some of the fluid reached the dusty bend and was then allowed to run back fermentation promptly started This made him state "The dust suspended in the air is the only origin and the first and essential condition of life in infusions" It was at this time also that he said "It is very desirable to carry these researches sufficiently far to prepare the way for a serious inquiry into the origin of disease" That showed the trend of Pasteur's thoughts about the germ theory of disease

The First Pasteurization

Pasteur's home was in Arbois—a wine-growing country He was naturally interested in the production of good wines and I can assure you from personal experience that Arbois produces good wine, for it was in November last on the occasion of the 50th anniversary of his death that we visited Arbois and indeed Pasteur's own vineyard there The wine producers were in trouble Many of the wines rapidly became unpalatable, sour, and ropy Pasteur investigated this in much the same way as he had with other fermentations He examined with the microscope the bodies found in healthy wine fermentations these were yeasts In the spoiled wine he found other minute bodies, and he showed that it was by the fermentations set up by these that the wine acquired a nasty taste Much more important from a practical point of view was his finding that these secondary fermentations could be prevented by slight heating of the wine This did not interfere with the flavour but completely stopped the spoilage This began the process which we know as pasteurization, to the great benefit of the wine industry of France Pasteur explained also the essentials of the process of making vinegar Whether made in the French way in casks or in the German way by slowly trickling wine over beechwood shavings was the same—a minute organism, the *Mycoderma aceti*, provided the ferment, but it required plenty of air for its action So the vinegar industry also benefited

Pasteur's work now took a new turn when his friend and supporter, the famous chemist Dumas, who came from the silk country, implored him to go there and investigate

disease which was destroying the silkworms and ruining the country. Pasteur pointed out that he knew nothing of silkworms or their diseases, but Dumas had the greatest faith in the genius of his younger colleague and managed to persuade him. I have not time to go into details of Pasteur's work on silkworms—how he collected information about their life history, how he examined them, healthy and diseased, under the microscope, how for a long time he was confused by the presence of two distinct diseases, or how he finally showed that it was possible to obtain and perpetuate healthy broods by selection of healthy stock and by cleanliness. In spite of the fact that in the middle of this work he was stricken with a form of paralysis from which he never recovered he was able in the space of five years to convince the silk growers that his methods were sound, and the silk industry of Europe was restored to prosperity.

After the Franco-Prussian war in 1871 Pasteur went on a holiday to his friend Duclaux at Clermont Ferrand. There was a large brewery near by. Pasteur, as always, was interested in the fermentations. Like the making of wine and vinegar, beer-making had been largely a rule of thumb with little knowledge of what was happening, and the brewers found that often the beer would not keep. It got sour or even putrefied. Pasteur with his indispensable microscope examined deposits from good beer and bad beer and noted the differences. Then he wanted to extend his observations to the larger English breweries, and in the same year he came to London and paid his historic visit to Whitbread's. In Vallery Radot's life of Pasteur it tells how he was well and courteously received, but instead of just seeing round the brewery he wished to see some of the barm of the beer. After examining it with the microscope he suggested that it was not too good. This made them sit up and take notice, for they already knew all was not well. Then he examined other batches, and could say from his simple microscopical examinations whether they were good, bad, or indifferent. He made such an impression that when he returned a week after Whitbread's had purchased a microscope and were beginning to control their fermentations. This microscope is becoming well known from the advertisement at present in the London tube stations, and is actually in this Pasteur exhibition in the Science Museum. This immediate acceptance of new ideas and controls was certainly to the credit of Whitbread's.

Just as with wine, Pasteur found that the souring of beer was due to a secondary fermentation with contaminating microbes. The pure brewers' yeast produced the essential fermentation which made good beer, but if the vessels were contaminated with the souring microbes these grew out later and spoiled the beer. Again, just as with wine, Pasteur found that heating the beer for a short time to 55° to 60° killed these contaminations. This was the origin of pasteurized beer.

It was in 1873 that Pasteur entered new fields by being elected (by one vote only) to the Academy of Medicine. Little did the academicians know when they admitted this chemist of 53 years of age that in another ten years he would have revolutionized many of their ideas.

In his studies on fermentation he had always in his mind that many human ailments were due to microscopic living objects (the word microbe was only introduced a few years later), and human infection had been forcibly brought home to him by the death of two daughters from typhoid fever. By this time Lister had, as a direct result of Pasteur's publications, introduced antiseptic surgery and was creating a revolution in that art. Other workers were contributing to our knowledge of what we may now call microbes, and the "germ theory" was being promulgated.

Davaigne had demonstrated what he called the "dium" of anthrax. Koch had grown it outside the body and demonstrated its character and mode of growth. It was only in 1877 that Pasteur, in collaboration with Joubert, commenced his work on anthrax. He cultivated a drop of anthrax blood through many flasks of culture medium so that anything dead in the original blood was diluted to extinction. After nine passages it was calculated that the original drop of blood had been diluted in a volume of fluid equal to the volume of the earth, and Pasteur did not stop at nine passages—he did many times nine. The last of these cultures was just as infective for rabbits and guinea-pigs as was the first one. He could then state positively that the bacteridium was the real infecting agent.

Other diseases were being connected up with definite microbes, and one of these, chicken cholera, had an enormous effect on subsequent developments in medical and veterinary practice. Pasteur isolated a microbe from fowls suffering from this disease, and he and his associates had shown that healthy fowls inoculated with cultures of this microbe contracted the disease and died. But on one occasion old cultures were used for these inoculations instead of fresh ones. The fowls did not die. The microbes in the cultures were alive, but for some reason they did not kill the chickens. They made new cultures and again inoculated the fowls—some of the survivors of the last experiment and some fresh ones, the previous survivors again survived, but the fresh ones got the usual chicken cholera and died.

Attenuation and Immunization

A less observant man might have passed this by, but not Louis Pasteur. He recognized that he had by the injection of the old culture immunized the fowls against the disease. Here was a new method of preventing infection. Cultures had first to be attenuated—that is, altered in some way that they do not kill the animals. Then when injected into the animals they give the animal protection, not death. Then Pasteur applied these methods to anthrax, a disease which was killing thousands of cattle and sheep. He had to find out how to attenuate his cultures so that they would not kill the animals. This he did by growing them at a higher temperature than normal. With vaccines made from microbes grown at these higher temperatures he found he could protect animals. But there was disbelief, as there always is with something startling or unusual. How could a chemist without veterinary or medical qualifications discover these things? He was challenged to one experiment to prove his statements and he readily accepted.

On a farm, Pouilly le Fort, 25 sheep and 6 cattle were inoculated with Pasteur's vaccine and the same number were left untouched. Two weeks after the second vaccine injection all were injected with a virulent culture that was known to cause the disease. Two days after, on June 2, 1881, there was an enormous concourse of people to see the results—senators, scientists, newspaper men, and others. The result was a phenomenal success. All the uninoculated animals were dead or dying while all those inoculated with Pasteur's vaccine were alive and well. I cannot do better than tell you the result in Pasteur's own words from a letter to his children written on the morning of June 2, 1881, before he left Paris to see it himself. "The telegram tells me that when we arrive at 2 o'clock this afternoon all the non-vaccinated subjects will be dead. 18 were already dead this morning and the others dying. As to the vaccinated ones they are all well." For Pasteur 1881 was a memorable year, so it was for me, for it was then I was born.

Chicken cholera and anthrax have been defeated—erysipelas was successfully tackled, and then it

to all infections was, 'Find the microbe and make it innocuous.' And for Pasteur a vaccine was synonymous with an attenuated living culture. At that time rabies or hydrophobia was much more prevalent than it is to-day, it was a dreaded and fatal disease. It was known that it followed the bite of a rabid dog, but beyond that there was complete ignorance. (We in Britain know little of hydrophobia. The quarantine precautions on dogs wiped it out, and we shall be free so long as there are no foolish persons who from mistaken sentimentality deliberately defeat this quarantine.) Pasteur set to work on rabies. He injected saliva from a child suffering from the disease into rabbits. They died, and some of their blood injected into other rabbits was likewise fatal. In the blood of these rabbits microbes were seen, but Pasteur was not deluded as were some others into the belief that he had discovered the microbe of rabies. He found he could get the same result with saliva of children suffering from other diseases or even with saliva from healthy people. Actually he had discovered the pneumococcus—the microbe usually responsible for pneumonia. The actual microbe of rabies eluded him. He could not see it with his microscope. That is not surprising, for we now know that it belongs to the class of viruses which are so small that the ordinary high-power microscope does not reveal them. But he was not beaten. The nervous system of dogs was obviously affected, so he went to the nervous system for his material. He injected material from the brain of a rabid dog into healthy ones and reproduced the disease after the usual incubation period. Then his assistant Roux injected similar material into the brain of a dog, and it became rabid in only fourteen days. The infective agent was concentrated in the central nervous system.

There is not time to go through the hundreds of experiments which Pasteur and his collaborators made, but they found that brain tissue from a rabid dog injected into a rabbit, and then from rabbit to rabbit, became more and more virulent until it reached a certain state when it remained constant. The spinal cords of the rabbits infected with this "fixed virus" were taken out and dried for various times. The longer they were dried the less virulent they became. The dogs were immunized by injection of an emulsion of a piece of the rabid spinal cord which had been dried for 13 days. Next day a piece which had been dried for 11 days was injected, and so on till the dog received the fresh virulent spinal cord. They did not get rabies, and subsequent attempts to give them rabies failed. They were injected with infective material from mad dogs. They were bitten by mad dogs, and they remained well. They had been successfully immunized.

One problem had been solved. Dogs could be immunized against rabies. But what to do? It was an impossible task to immunize the millions of dogs in France. But was it possible to immunize a human being in the same way during the incubation period—that is between the time he was bitten and the time the symptoms appeared? The incubation period was long—several weeks—so possibly there was time, but the question was not yet solved as to whether the injection of the dried rabbit's spinal cord which did not infect the dog would be equally harmless to man. At last Pasteur's hand was forced. From Alsace came Mme. Meister, bringing her boy Joseph, who had been severely bitten by a mad dog, and imploring Pasteur to save him from the dreaded disease. Pasteur immunized Joseph Meister as he had done his experimental dogs. The injections were harmless, and Joseph Meister did not get rabies. At last it had been shown that it was possible to protect man against infective disease even after the infection had occurred. The immunization of Joseph

Meister was not a flash in the pan. It was successfully repeated on many others, and Pasteur's laboratory in Paris became the mecca of people from all over Europe who had been bitten by rabid dogs.

This may be regarded as the culmination of Pasteur's great work. Famous he had been before, but now he was a national hero. Subscriptions were invited for the foundation of an institute in which he could carry on his great work, and they poured in from all over the world. The Pasteur Institute was erected in the Rue Dutot (now renamed the Rue de Docteur Roux after Pasteur's great collaborator). On Nov. 14, 1888, the new institute was opened by President Carnot. A quotation from Pasteur's speech on that occasion summarized his philosophy.

'To believe that one has made an important scientific discovery, to be in a fever to announce it and to restrain oneself, to force oneself to confute one's own experiment, and only to proclaim a discovery when all contradictory hypotheses have been disproved—yes, this is an arduous task. But when after very many attempts one has at last arrived at certainty, on experiences one of the greatest joys the human mind can feel and the thought that one will add to one's country's glory makes this joy greater still.'

Another quotation from the speech.

I would say that two contrary laws seem to be wrestling with each other nowadays: the one a law of blood and death, ever imagining new means of destruction and forcing nations to be constantly ready for the battlefield—the other a law of peace, work, and health, ever evolving new means of delivering man from the scourges which beset him. Which of these two laws will ultimately prevail God alone knows.

How true to-day!

In 1892, on the occasion of his 70th birthday, an enormous crowd gathered in the theatre of the Sorbonne. Our Royal Society was represented by Lord Lister, who said "Truly there does not exist in the whole world an individual to whom medical science owes more than to you." That was said 53 years ago. It is true to-day except that Pasteur is now with us only in spirit.

In the new institute Pasteur was able to see his assistants and collaborators carry on his great work. His health failed, and on Sept. 28, 1895, he died in peace. His body lies in the Pasteur Institute, the useful monument erected for him in his lifetime. His spirit animates workers in microbiology throughout the world.

In succeeding years Pasteur institutes were opened in many parts of the world to carry out Pasteur's methods and, quite apart from the immediate benefits which this gave in the preparation of vaccines and the protection of man and animals, they have advanced knowledge in many ways, as can be seen from a study of the exhibits in this beautifully arranged Pasteur exhibition.

The introduction to the catalogue of this exhibition is written by Pasteur's illustrious grandson, Prof. Pasteur Vallery Radot, who is not only a great physician but a great partisan. In this he points out how throughout his scientific life Pasteur was encouraged and assisted by British scientists—Tyndall, Lister, and others. He tells of his emotion at witnessing the embrace of Pasteur and Lister on the occasion of his jubilee with these words: "Was not this gesture a symbol of the bonds uniting our two nations?"

It is good to see the line of the great Pasteur so worthily carried on.

We have surveyed Pasteur's work. Let us see briefly how it has affected us in our lives to-day. People have speculated on which of Pasteur's many discoveries is the most important. It is very difficult to say. T

hemist may say it is his early work on crystals, the pure microbiologist, that it is his refutation of spontaneous generation, the industrialist, that it is his work on fermentation of wine and beer, the agriculturist, that it is his study of silkworm disease or the protection of animals against anthrax and other diseases.

A physician will be doubtful, for almost all of them have assisted him in his work. As a microbiologist and a physician I have the greatest admiration for his last great work on rabies. It was difficult, he had so little to go on, it was so methodically tackled, and it was so successful. His work on fermentations led directly to the cure of diseases of wine and beer. There are teetotalers who may think this is a misfortune, but especially in these disturbed times such beverages seem to provide solace. But his work did more than that. The abnormal fermentations of wine and beer were cured by a process which became known as "pasteurization." We hear of pasteurization now, but it is the pasteurization of milk we hear of. It is by this process of pasteurization that much milk-borne disease is prevented in our large cities, and this we owe to Pasteur's studies on alcoholic liquors.

The Antiseptic System

There was another and even more important direct outcome of Pasteur's fermentation work. Lister, who was then working in Glasgow, read Pasteur's communications, and in them he saw the possibility of keeping germs out of the operation room. In those days nearly all operation wounds were septic and many gangrenous. We have had handed down to us the phrase "laudable pus." Then it was a sign that the patient would probably recover. Now of course pus of any kind, "laudable" or otherwise, is a reflection on the surgeon's methods.

There had been many explanations offered as to the origin of this putrefaction of wounds, but it was Pasteur's work which made Lister see the true light. The infection came from outside, so Lister sterilized as far as he could with carbolic acid and other antiseptics his hands, his instruments, and his dressings. He even used a carbolic spray to sterilize the air. Thus he revolutionized surgery and became one of the greatest figures in British medical science. It was in 1874 that Pasteur received a letter from him saying: 'Allow me to take this opportunity of thanking you most heartily for having shown me, by your brilliant investigations, the truth of the germ theory of putrefaction, and for having thus acquainted me with one principle which can lead the antiseptic system to final success.' How much life and suffering has been saved by the methods which Lister and his successors initiated as the result of Pasteur's teaching!

In his studies on spontaneous generation and on bacteria he and his colleagues introduced methods which we all use to-day. Notable among these was the introduction of the autoclave for sterilizing material by steam under pressure. This is in constant use to-day in hospitals, in laboratories, and in industry.

Let us now come to the later and most directly medical work—the protection of animals and man against infection. The experiment on anthrax at Pouilly le Fort in 1881 proved without a shadow of doubt that animals could be protected with vaccines. That was settled once and for all, but we still argue about the details of vaccine therapy, and even now there are hundreds of laboratory workers engaged in exploring the uses of various vaccines and the best way of producing them.

All Pasteur's vaccines were living attenuated cultures, and it was only in the case of rabies that they were used on man. Living vaccines have drawbacks. Although they

can be attenuated so that they do not cause disease, requires care and skill, and, human nature being what it is, sometimes one is a little careless, and instead of a living vaccine protecting it might actually give rise to infection. As "superior" human beings we might occasionally allow that with cattle, pigs, or sheep, but no one would willingly look with complaisance on the possibility of one's child succumbing to the injection of a protective vaccine. But after Pasteur's time it was found that even if the microbe in a vaccine were killed protection against many diseases could be obtained. The great advocate of immunization with killed cultures was our countryman and my own master, Sir Almroth Wright. At the end of the last century he showed that typhoid fever could be prevented by inoculation with a killed typhoid vaccine. This was a safe procedure. The microbes in the vaccine were dead and could not infect. Now the use of typhoid vaccine is world-wide, and this great scourge of armies in the field has been reduced to comparatively negligible proportions. This is not all due to typhoid vaccine. Hygiene has an important place, but so has the vaccine. In many other bacterial diseases, also, killed bacterial vaccines have been used and are being used extensively. The use of these dead vaccines was further extended by Wright to the cure of infections which had already established themselves, and large numbers of these infections have been so treated.

Rabies was in a rather different category. That was a virus disease. Pasteur could not find the microbes, so his vaccine was an emulsion of infected tissue containing a large amount of the virus. This same procedure is used to-day in virus diseases such as dog distemper, yellow fever, and influenza. Instead of the dried rabbit's spinal cord which Pasteur used, the vaccine may be made from a mouse's lung or from material obtained from a chick embryo infected inside the eggshell. Some of these virus vaccines confer a solid immunity, and as we become more and more acquainted with the viruses we shall be able to produce more and more potent vaccines. By means of the electron microscope we can now see the viruses. By various methods we can measure them, and we are gradually learning more and more about them, but the general principle of the virus vaccine to-day is much the same as that of Pasteur's original rabies vaccine.

Antitoxins and Antibiotics

This process of immunization has proceeded beyond vaccines. In Pasteur's lifetime his colleagues, Roux and Yersin, discovered a powerful toxin made by the diphtheria bacillus. Animals immunized with this toxin produced antitoxin, and every child suffering from diphtheria is now treated with this antitoxin. Much more recently it was found that this poisonous toxin could be treated with formalin, when it ceased to be poisonous but still evoked in animals the production of antitoxin. The name of Ramon of the Pasteur Institute is associated with the immunization of children by injection of this anatoxine, as he called it, or toxoid as we call it here. Many people have improved the method, it is harmless, and it certainly gives a good protection against diphtheria. It is a very serious responsibility for a parent at the present day to refuse to have his or her child immunized against this serious infection. The same method is used for protecting against tetanus or lockjaw, and it was Ramon who showed its merits in the immunization of man. In the recent war all our armies were immunized and there was almost no tetanus. Thus another scourge of war was eliminated.

Then there is another method of dealing with bacterial infection in which I am myself particularly interested—mean penicillin. Penicillin belongs to the class

APR

stances called antibiotics. These are substances produced by living bodies which have the special property of killing or interfering with the growth of micro organisms. It was Pasteur and his colleague Joubert who in 1877 first described this phenomenon of bacterial antagonism. Pasteur did not pursue this subject, he had other more obviously important matters in hand. If he had gone on with it, who knows but that we might have had penicillin in the last century or perhaps even before I was born.

I have said nothing about the laboratory accommodation which was provided for Pasteur during his life. At the end perhaps it was adequate, but in the earlier years when he made his great studies on fermentation it was lamentable. Nowadays it would be considered disgraceful that any scientist, much less a scientist already famous, should be so badly housed. An American newspaperman described my own laboratory as like the backroom of an old-fashioned drug store, and yet my laboratory is adequate and reasonably modern. What would they have said about Pasteur's attic? It only shows that it is not the grandeur of the laboratory but the grandeur of the man that matters, and that the marble halls so common in certain parts of the world are quite secondary to the brain of the worker.

We have seen something of Pasteur's scientific accomplishments. We have seen something of what they have led to, and something of the debt which the world owes to his genius and perseverance. Not even a partial paralysis could daunt him, and much of his best work was done after that illness. Pasteur was the founder of a science, "microbiology." He was a chemist who gradually became a biologist. His successors were mainly biologists, but in recent years microbiological science is becoming more and more chemical. In the short space of 70 years it is completing a circle from chemistry through biology to chemistry again. But Pasteur was not only a scientist. He was an artist of considerable merit and he was a very human man, adoring his family and his home and his country. His father, his wife, his children, and his grandchildren were very dear to him, and it is a great pity that his grandson, Professor Pasteur Vallery Radot, could not be with us in London to-day.

There have been admirers who claimed for Pasteur more than he had done. That is unnecessary and does not help his memory. He did in his lifetime sufficient to make ten men great. That is enough. It is a pity to gild the lily. He was one of those rare individuals thrown up at intervals throughout the world's history to restore order out of chaos. He was a great Frenchman, but it is not only France which has to thank him. The whole world is deeply in his debt, and we here in London take this opportunity of rendering homage to the memory of our great benefactor, Louis Pasteur.

Negotiations have been completed for close co-operation between the Prince of Wales's General Hospital, London, N., the largest voluntary general hospital in North East London, with 260 beds, including its convalescent home at Nazeing, Essex, and the Bearsted Memorial Hospital, London, N., which is a voluntary maternally hospital. The first stage of this hospital's new building at Stoke Newington is now rapidly nearing completion and will be opened in July. The new building when completed will have a total of 100 maternity beds and will be the most modern maternity unit in Britain. It is proposed that in addition to general medical and surgical service, already supplied by the Prince of Wales's General Hospital, these two hospitals will eventually provide a complete obstetric and gynaecological service for the district. With this association the following hospitals will now participate in the North London Postgraduate Medical Institute, which provides senior postgraduate teaching under the aegis of the British Postgraduate Medical Federation of the University of London: Prince of Wales's General Hospital, North Middlesex County Hospital, Chase Farm Hospital, North-Eastern Fever Hospital, Bearsted Memorial Hospital.

EFFECTS OF CERTAIN DIETS ON LOSS OF NITROGEN IN URINE EXPERIMENTAL BURNS

BY

E. A. SELLERS, M.D. AND C. H. BEST, M.D.

With the Technical Assistance of J. C. Barlow, B.Sc.

(From the Banting and Best Department of Medical Research, University of Toronto)

After burns or other injuries the urinary excretion of nitrogen may be definitely increased. Cuthbertson (1936), Peters and his associates (Leach *et al.*, 1943, Croft *et al.*, 1945), and others have observed that the extent of burning affects the amount and type of nitrogenous material excreted. Investigations by Taylor and his associates (1943), Co Tui *et al.* (1944), and Elman, Cline, and Davey (1943) have shown that large amounts of nitrogen must be administered after extensive burns if nitrogen equilibrium is to be maintained. Croft and Peters reported that the increase in nitrogen loss after burns could be reduced substantially by giving methionine, a protein supplement, to rats maintained on a moderate low-protein diet. In their studies, rats of either sex, weighing from 100 to 150 g., were placed on a basal diet containing 10% casein and 10% dry yeast until a satisfactory nitrogen balance was obtained. Under either a standard burn covering approximately one-third of body surface was produced in water at 73°C., and the effects of various supplements added to the diet were studied. In control groups of animals an increased nitrogen excretion in the urine occurred. In groups receiving a supplement of 1% methionine or 18% casein little was noted, while groups receiving supplements of L-cysteine, or an amino-acid mixture including only L-methionine showed no significant difference in nitrogen excretion from the controls. This observation that the amino-acid can replace the extra protein supplement supports directly the hypothesis that the nitrogen loss is due to the raiding of tissue protein molecules for "methionine." The finding that neither alanine (as a source of amino groups) nor cysteine (as a source of sulphur) had the same effect suggested to Croft and Peters that the well-known function of methionine—that of methylation—was responsible for the effect observed.

Experiments have been performed in this laboratory with rats maintained on both normal and deficient diets. The results confirm only in part, and extend and modify the conclusions of Croft and Peters. Prof. Peters has examined some of the results of our experiments, and his comments have been most helpful.

Experimental

1. First Methionine Series.—Young female rats of the Wistar strain, weighing between 100 and 150 g., were placed on a diet of 15 g. of fox chow a day until a relatively constant urinary output of nitrogen was obtained. This usually occurred in from 10 to 14 days. Under anaesthesia they were then subjected for a period of 30 seconds to water at 73°C., in a manner similar to that described by Croft and Peters. Most of the animals had a burn amounting to about one-third of the surface area of the body, was immersed in heated water. On the day after the burn and daily thereafter a buffered solution of methionine equal to 1% of the diet was injected subcutaneously. Six of the nine rats used in the experiment were weighed daily and urinary nitrogen estimated by the method made at 48-hour intervals for ten days after the burn.

Finely ground food was placed in small dishes outside the individual cages in such a manner that the rat could not enter the dish or readily scatter the food. After the first day or two in the cages little or no scattering occurred. The circular bottoms of the cages were of stainless fine-mesh wire screening. Urine dropped through upon waxed funnels and ran into test-tubes containing concentrated sulphuric acid. Macro-Kjeldahl nitrogen estimations in duplicate were done on a 5-ml aliquot of the sample after it had been made up to a standard volume. A pledget of fibre glass was placed in the funnel as an additional safeguard against faecal or food contamination. The weight range of the rats was fairly narrow, and grouping was carried out by using a table of random numbers. All animals received the same amount of food, the control and test groups consumed approximately the same amount.

2 Second Methionine Series—The first experiment was repeated, using 20 female rats ranging from 140 to 160 g in weight. Since in the first experiment no significant rise in nitrogen excretion took place after burning, a temperature of 85° C was selected instead of 73° C. Twelve animals were given a supplement of methionine amounting to 1% in the 15 g of ground stock diet fed daily. In other respects the procedure was similar to the previous study.

3 Third Methionine Series—Twenty-one adult female rats, 170 to 205 g, were divided into three groups of seven. They were fed a low-protein (12%) diet (Table I, Diet 1) *ad libitum* for seven days, and then given the amount of their average daily consumption for a further seven days before burning. One group received the basal diet throughout. Another group received the basal diet plus a supplement of methionine (1% of diet) throughout. The third group received the basal diet until the day of the burn, and were then given a diet supplemented with methionine. Burning was carried out as before, in water heated to 55° C. In this experiment, however, nitrogen estimations were performed on the collected urine from each group rather than from individual rats. Therefore only a group figure is available.

4 Fourth Methionine Series—Twenty-three young female rats weighing from 70 to 90 g were fed 8 g a day of a diet deficient in methionine (Table I, Diet 2). The

TABLE I—Diets in Burn Experiments

Diet 1	%	Diet 3	%

Choline chloride	0.3	Vitamin D	at least 75 i.u.
Phenylalanine	0.3		

procedure followed in experiments 2 and 3 was continued, with the exception that the temperature was decreased to 75° C. In a preliminary experiment with this diet, burning at the higher temperature had resulted in a high mortality. After the burn collections were made at three instead of five 48-hour intervals. Eleven rats received a methionine supplement and twelve acted as controls.

5 Fifth Methionine Series—Twelve adult female rats, 180 to 200 g, were fed 12 g a day of the same diet as in the fourth series. The procedure was similar to that described in the previous series.

6 Cystine Series—Young rats, 70 to 90 g, were fed 8 g a day of the same basal diet as in the fourth and fifth methionine series. The experimental animals received a supplement of cystine equivalent in sulphur content to the methionine supplement formerly given (810 mg per 100 g cystine). Choline chloride in an amount of 0.34 g % was present in the diet. The procedure followed was similar to that described above. Ten rats received the cystine supplement, while eight acted as controls and received the basal diet only.

7 Lysine Series—A final experiment was performed in which young female rats weighing from 70 to 96 g received a diet (Table I, Diet 3) designed to be deficient in lysine. This diet, however, contained 17% protein, in contrast to the previous basal diet, which contained only 14% protein. The experimental procedure and dietary intake (8 g a day) remained the same.

Results

In the first experiment, in which burning was carried out at 73° C, there was no appreciable increase in urinary excretion after the burn, either in the control or in the experimental group.

In experiment 2, in which a temperature of 85° C was used to produce the burn, a significant increase in the average daily urinary nitrogen excretion occurred after burning. There was no significant difference between the

TABLE II—Amino acid Composition of Diets (mg per 100 g diet)

Amino-acid	Diet No 1	Diet No 2	Diet No 3	Estimated Requirement (Rose 1937)
Methionine	348	371	457	600
Threonine	548	620	637	600
Valine	708	768	739	700
Leucine	1216	1256	2826	900
Isoleucine	710	880	871	500
Arginine	550	752	527	200
Histidine	290	342	297	400
Lysine	930	1060	733	1000
Phenylalanine	660	610	1011	700
Tryptophan	220	203	162	200
Cystine	88	101.3	137	

After burning rats in the experimental group were fed Diet No 1 supplemented with 1% methionine.

In Diet No 2 *dl*-phenylalanine—300 mg per 100 g diet—was added raising the intake of this amino acid to 910 mg per 100 g diet. After burning 1% methionine was added to the diet of the experimental group. In the experiment involving cystine an amount equivalent in sulphur content to 1% methionine—namely 810 mg per 100 g—was added in place of the methionine.

In Diet No 3 levels of methionine and histidine were raised by adding 119 mg methionine and 107 mg histidine per 100 g of diet. After burning lysine 367 mg per 100 g diet in the form of 458 mg of lysine hydrochloride, was added to the diet of the experimental group.

TABLE III—Mean Increase in Daily Nitrogen Excretion (in mg of N)

Series	Control	Treated	P Value*
Methionine 2	63.1 ± 9.1 (8)	56.8 ± 11.0 (12)	0.7
" 4	45.7 ± 3.7 (12)	31.6 ± 4.7 (11)	0.02
" 5	37.4 ± 12.5 (6)	13.0 ± 8.7 (6)	0.15
Cystine	25.0 ± 2.1 (8)	28.2 ± 5.6 (10)	0.63
Lysine	50.2 ± 3.4 (6)	52.8 ± 4.6 (5)	0.69

* Fisher R. A. *Statistical Methods for Research Workers* Edition 8 Oliver and Boyd 1941.

methionine-treated group and the control group— $P=0.7$ approx (Table III). After burning, an immediate increase in body weight occurred in both experiments.

In series 3, as figures are available only on the excretion of nitrogen by groups of animals, it is not possible to analyse the results satisfactorily. Nevertheless, the figures give no indication that on this diet the supplementary methionine decreased the loss of nitrogen. Table II shows that the diet was deficient in several amino-acids besides methionine.

In series 4, with a specific deficiency of methionine in the basal diet given to young rats, there was a significant

difference ($P=0.02$) in the increase of nitrogen excretion after burning between the methionine-treated group and the control group. The group which received a supplement of methionine (1%) in the diet showed less increase in nitrogen excretion than the control group (Table III).

In adult rats receiving the same methionine deficient diet (series 5) no significant difference in nitrogen excretion was noted— $P=0.15$, approx (Table III).

A comparison of the increase of nitrogen excretion in the control and experimental groups of the cystine series (No. 6) shows no significant difference ($P=0.63$). Although the sulphur deficiency of the diet was made up by a cystine supplement equivalent to methionine 1%, and an adequate amount of choline was present in the diet, the effect of methionine noted in series 4 did not occur (Table III).

In the final experiment, when the lysine deficiency in the diet was made up, the increase in nitrogen excretion after burning remained of the same order as that of the control group. When compared statistically a P value of 0.69 was obtained (Table III).

Discussion

Cuthbertson (1936) found that administration of diets rich in certain proteins and of a high calorie value decreased the loss of nitrogen after injury. Croft and Peters (1945) reported that administration of the single amino-acid methionine was capable of replacing good-quality protein in reducing the nitrogen loss. The present experiments confirm this action of methionine, but suggest strongly that it occurs only when a deficiency of methionine exists in the diet. In the preliminary group of experiments, when rats were fed the laboratory stock diet (20% protein) and burned at 73°C , little increase in nitrogen excretion took place, but at 85°C a significant increase did occur. On a low-protein diet burning at 75°C produced a definite increase in nitrogen loss both in control and in treated groups, but on this diet, using 85°C , a high mortality was encountered. When methionine (1%) was added to the chow diet in the first experiment no significance could be attached to the difference in nitrogen excretion between experimental and control groups.

When a methionine-deficient diet was fed to young rats (in which the methionine requirement is probably higher than in adult animals) and a methionine supplement (1%) was added after burning, the groups fed the supplement excreted less nitrogen than did the untreated group. With fully grown animals no such difference existed, though the P value (0.15) might be considered suggestive in view of other experiments.

From these results and a study of the diet used by Croft and Peters, it is suggested that their basal diet (14% protein) was probably deficient in several amino acids, and particularly in methionine.

In the case of the cystine-supplemented diet no significant difference in nitrogen excretion from the control group could be demonstrated. An amount of sulphur equivalent to the methionine supplement was present and adequate choline (as a source of methyl groups) had been included. The suggestion that the activity of methionine is associated with its methylating function is not supported by this result. The addition of lysine to a lysine-deficient diet likewise failed to influence the nitrogen excretion.

It is difficult to draw general conclusions from nutritional experiments of this type. The nutritional demands under abnormal conditions such as existed in these experiments are not well known. It is not clear whether it is the general level of protein intake, or the ingestion of specific com-

binations of essential amino-acids or of certain individual acids, which is most directly concerned in preventing tissue breakdown or in hastening repair after trauma. The demands for growth and other body functions and the presence of other essential food factors no doubt affect these requirements. It does seem safe to assume that if a relative deficiency of methionine exists, whether due to dietary deficiency or to metabolic requirements, its replacement may reduce the amount of nitrogen lost after burning under certain specific conditions. The experimental evidence thus far produced suggests that this action is a specific effect of methionine, and cannot be produced by the administration of cystine plus choline.

In both dietary and toxic types of liver injury supplements of methionine or choline confer a degree of protection to animals fed basal diets low in protein (Miller and Whipple, 1942; Daft *et al.*, 1942; Messinger and Hawkins, 1940). Drill and Loomis (1946) have reported that no protection against liver damage due to carbon tetrachloride is given when methionine is added to a normal diet. However, in experiments involving the use of the lipotropic agents in experimental cirrhosis, one of us (E. A. S.) has produced evidence that a methionine deficiency may exist in relatively high (35%) mixed protein diets. In this case a supplement of choline or methionine produced a dramatically favourable effect.

The experimental basis for the use of methionine in the treatment of burns would seem to limit its use to cases in which an absolute or relative deficiency of this amino acid exists.

Summary

A methionine supplement (1%) to a stock diet did not reduce the urinary loss of nitrogen after burning.

When a methionine deficiency existed in the basal diet of young rats, however, a supplement of methionine lowered the nitrogen excretion.

When similar diets were given to adult rats a suggestive but not statistically significant decrease in nitrogen excretion followed the administration of methionine.

Cystine (in an amount equivalent in sulphur content to the methionine supplement) plus an adequate choline intake was ineffective in reducing the nitrogen loss in young rats.

A lysine supplement added to a lysine deficient diet was also ineffective.

The experimental basis for the use of methionine in the treatment of burns would therefore appear at present to be limited to the application of the finding that methionine is effective in young animals receiving a diet very low in this amino-acid. With a more drastic dietary deficiency of methionine, or a more extensive injury, the beneficial effect of giving this amino acid to adult animals might be revealed.

We appreciate the help of Prof. C. C. Lucas of this department in planning the diets and experimental procedures.

RATIONS AND NUTRITIONAL NEEDS

BY

E R BRANSBY, Ph D

AND

H C MAGEE, M B, D Sc.

Before the introduction of bread rationing the amounts of nutrients present in rationed foods* gave an inadequate picture of the sufficiency of the diet available to individuals or groups because of the large contribution made by bread to the nutritive value. The main contribution of bread is in respect of calories, protein, and the B vitamins, and its inclusion among the rationed foods was a step of fundamental importance. The rationing of bread reduced considerably the flexibility of the national diet, for it was formerly the main elastic reserve whereby those with large appetites could readily satisfy their needs. With the introduction of bread rationing it became inevitable to provide an increased supply for those with large energy requirements. Energy needs depend not only on obvious factors, such as body size and intensity of work, which are physiologically predictable, but also on unpredictables inherent in the personality or constitution of the individual. Because of the multiplicity of factors, particularly the unpredictables, that determine the needs for energy, it is beyond the wit of man to devise a workable scale of energy allowances strictly applicable to each individual in a mixed community. The rationing scheme is necessarily based on the average requirements of sections of the population. These averages embrace a wide range of variations which cannot be fully and accurately provided for in a national scheme. It is therefore inevitable that the rations should vary in accordance with individual requirements from relative excess on the one hand to relative deficiency on the other.

The purpose of this paper is to compare the amounts of nutrients particularly calories, in the rations with the theoretical needs of different sections of the population, to ascertain the gaps between these two, and to examine the means whereby the gaps can be bridged.

One of the fundamental principles in the scheme of rationing is that it should provide the bulk of the essential nutrients required by mothers, children, and invalids (priority classes). Many of the foods of special value for these classes, such as milk and eggs, are also good sources of energy. Consequently, their rations yield a larger proportion of their energy needs than is the case with other classes so that the gap between the energy content of the rations and theoretical needs is smaller. Notwithstanding the rationing of bread there still exists considerable flexibility in the rationing system, and this derives from one or more of the following: (a) unrationed foods, (b) canteen school or similar extra meals, (c) the use of 'points' to the best advantage, including exchange of points into bread units (B.U.s) and (d) diversion of rations from family members with small needs to others with greater needs (the family pool).

(a) *Unrationed Foods*—The chief of these is potatoes, but they are relatively bulky: 16 oz. (454 g.) which is probably as much as the ordinary consumer ever eats yields only 260 calories. Fruit and vegetables are relatively poor sources of energy: 8 oz. (227 g.) which is a fairly generous daily amount, yields on the average only about 50 calories. There remain a few other sources and a few other foods of less importance the procurement of which depends upon a complexity of

factors, together they would probably yield not more than about 150 calories a day in normal circumstances.

(b) *Canteen and Other Meals*—Those who have access to public eating places could get almost any proportion of their requirements from this source, but permanent residents in hotels must surrender their ration books. School meals are planned to provide a maximum of 1,000 calories daily. Canteen meals and snacks could provide up to 1,000 calories or more daily.

(c) *Exchange of Points to B.U.s*—The food value obtainable from a given number of points is variable, but, generally speaking, better nutritional value can be obtained from spending points on simple things, such as dried pulses and sardines, than on luxury foods, such as expensive canned fruits and biscuits. Exchange of all points to B.U.s would produce an average gain of some 350 calories, or about 50 per exchanged point a day.

(d) *The Family Pool*—As pointed out below, the rations of young children provide in themselves more than enough calories for their needs. In addition, the energy needs of women and of old men are about 80%, or less, of those of the ordinary male, but the rations for all these are identical. It therefore follows that a family comprising one or more such people would have some spare rations to pass on to those with bigger appetites. For instance, about 100 calories a day would be provided by one ration of bacon and cheese, plus 1 oz. (28 g.) of fat weekly. These spare rations would, in addition, provide a "lubricant" for the greater consumption of unrationed foods such as potatoes.

Rations and Requirements Compared

Table I sets out the rations and allowances for different sections of the population, and Table II shows the amounts

TABLE I—Food Rations, Priority Allowances and Certain Expected Distributions per week (November 1946)

	Up to 1 year	1 year	2, 3 years	4 years	5-10 years	11-13 years	14-17 years	Normal Adult	Expectant Mother	Nursing Mother	Manual Worker (Male)	Manual Worker (Female)
Cheese (oz.)	2	2	2	2	2	2	2	2	2	2	2	2
Bacon (oz.)	3	3	3	3	3	3	3	3	3	3	3	3

Bread (oz.)	8d	8d	8d	8d	1/4	1/4	1/4	1/4	2/4	1/4	1/4	1/4
Meat (cost)	4	4	4	4	4	4	4	4	4	4	4	4
Jam (oz.)	7	7	7	7	5 1/2	5 1/2	3 1/2	2	9	7	2	2
Milk (pints)	3	3	3	3	4	4	4	4	4	4	4	4
Eggs (no.)	4	4	4	4	4	4	4	4	4	4	4	4
Dried egg (oz.)	4	4	4	4	4	4	4	4	4	4	4	4
Sweets (oz.)	8	8	8	8	8	8	8	8	8	8	8	8
Points (no.)	x	x	x	x	x	x	x	x	x	x	x	x
M/Food orange juice	x	x	x	x	x	x	x	x	x	x	x	x
M/Food cod liver oil	x	x	x	x	x	x	x	x	x	x	x	x

The distribution of milk and eggs to non-priority consumers has been taken as 2 pints and 4 per week respectively. Infants under 6 months do not receive the priority allowance of eggs.

For conversion into metric measures: 1 pint = 568 ml., 1 oz. = 28.35 g.

of nutrients derivable from the rations and compares these amounts (less deductions for losses of vitamins B₁ and C due to cooking) with the requirements suggested by the Technical Commission of the League of Nations, which we regard as the appropriate scale for the population of Great Britain.

The most noteworthy features of the comparison are: (a) *Children*. The rationed foods provide enough or more of calories, protein, and iron up to 10 years, (b) of vitamins A and C up to 5 years, and (c) of calcium up to 2 years. *Expectant mothers*. The rationed foods provide enough or more of protein, calcium, iron, and vitamins A and C. *Nursing mothers*. The yield of all nutrients from the rationed foods is less than requirements. *Adolescents (14 to 17 years)*. The amounts of all nutrients provided by the rationed foods are less than requirements. *Normal consumers and manual workers*. The amounts of protein, calcium, and iron in the rationed foods are rough-

* By rationed foods is meant those strictly rationed (e.g., meat, bread, fat, cheese, etc.) all 'points' and milk and eggs the distribution of which is controlled.

about the same as, and of all other nutrients less than, requirements

We now consider for each section of the population how the gaps between rations and needs can be made up. We confine our attention to energy—for brevity, and because experience of present diets has made it clear that, given all rations and enough unrationed foods to provide the energy requirements, the resultant diet is usually about sufficient in all the nutrients cited in Table II and in riboflavin and niacin, which are not included in the table.

Young Child—It is clear from Table II that if children below the age of 5 were to consume all their rations they would get more than enough energy without eating any unrationed foods at all. It is the general custom, however, and from the nutritional point of view one to be commended; that children from about the age of 2 participate in the family meals. In this way they would probably obtain about 100 calories or more daily, depending on age, from the unrationed foods. It follows that children below 5 years should have 500 or more calories a day to spare from their rationed foods to go into the family pool.

School-child and Adolescent—Up to the age of 14 years* the feeding of the school-child should present no problems. Indeed, between 5 and 10 years the rations alone yield more calories than are needed, and if a school meal is eaten the family pool could be enriched by the equivalent in calories

about reach his target. But if he requires more than 3,000 calories a day, as an active youth of about 16 may well do, it would be necessary to get a substantial helping from the family pool and/or change more points into BUs, to the detriment of the diet in a qualitative sense. If the adolescent's occupation entitles him to the designation "manual worker" then the extra 12 oz (340 g) of cheese and six BUs (630 calories daily) which he can get should make it easily possible for him to satisfy his needs.

Normal Consumer—We need only consider the normal male. The energy requirement of the average man in a community as given by the League of Nations is 3,000 calories, a figure which includes all grades of work from sedentary to very heavy. For the purposes of the bread rationing scheme most classes of manual workers from moderate to very heavy are included in the category of manual workers. The normal male consumer therefore embraces the large group of men whose activities vary from sedentary to light work, probably a very small number of the moderate work category, and a large number of oldish men whose requirement is mostly less than that of the sedentary class. Weighing up all these varying requirements, it seems reasonable to place the average needs of the normal male consumer at about 2,600 calories, but it should be clearly understood that this average figure covers a range which may well be of the order of 2,200–3,000. At

A = Nutrients provided by foods in Table I

B = Requirements on the League of Nations scale

and all nutrients. The gap between rations and needs is only about 300 calories between 11 and 13 years. This gap could be more than made good by the school meal, which is scheduled to supply up to 1,000 calories (Circular 1571, 1941, Board of Education). For adolescents between 14 and 17 years the gap is of the order of 800 calories or more. Adolescents who remain at school up to 18 and partake of the school meal should have no difficulty in satisfying their requirements. Those who leave school at 14 and go to work in a place provided with a canteen likewise should have little difficulty. For those with no such facilities it may not be easy to make good the gap of 800 or more calories. Certain categories of adolescents living in schools and colleges which are not eligible for school meal allowances can, on special application, get an extra allowance of three BUs weekly. These would provide about 215 calories daily, leaving still about 600 or more to be made up. How this could be done is shown in Table III. The special allowance of three extra BUs applies only when the student is in residence, when on vacation he is in exactly the same position as the adolescent who lives at home all the time and has no canteen or similar facility. It can be seen from Table III that such people may find it difficult to satisfy their needs unless there are younger children in the family with spare rations. The table shows that if he changes six of his eight points into BUs and eats 1½ lb (680 g) of potatoes a day he can just

the lower end of the range there would be no difficulty in securing enough, and there would almost certainly be a surplus to put into the family pool. At the top end of the range, however, there might be some difficulty in satisfying needs. If we place the needs of the ordinary male consumer at 2,600 calories he has to get 760, say 800, calories from unrationed foods or in other ways (see Table III). A meal taken in a restaurant should yield 600 calories or more, thus leaving about 200 calories to be made up from potatoes, etc. The figures in Table III make it clear that he should have little difficulty in doing this. If, however, he cannot get a restaurant meal he would have to change six of his eight weekly points into BUs and eat as much as 1½ lb (680 g) of potatoes daily to reach his requirements. This exchange would, however, impoverish his diet in qualitative sense, and if he were to forgo the exchange he could probably get no more than about 500 calories from unrationed foods, thus leaving a gap of, say, 300 calories to be filled. Failing a family pool to dip into he would have to change all his points into BUs, eat more potatoes and other things such as sausages and fish if he can get them, or else go hungry.

Expectant Mother—The rations of the expectant mother leave a gap of about 550 calories to be made good by potatoes, vegetables, fish, sausages, and offal, changing six points into BUs, and, if need be, by dipping into the family pool. The way in which her diet could be brought up to the desired level of 3,000 calories is shown in Table III.

* The school leaving age has now been raised to 15 years.

Table III It is assumed that she can eat $1\frac{1}{2}$ lb (680 g) of potatoes daily. If she prefers bread she could obtain only enough to replace 1 lb (454 g) of potatoes by changing five more points into BUs, but the variety of her diet would suffer. This situation, however, would only arise with the first child. Children in the family up to about 14 would provide a substantial reserve of rations.

Nursing Mother—The rations of the nursing mother leave a gap of about 900 calories. Her infant's rations amount to about 1,800 calories, whereas its requirements are about 800. The nursing mother could therefore meet all her needs from the rations of herself and her infant without consuming any unrationed foods.

Manual Worker—The male manual worker is left with a deficit of about 1,200 calories to make up. Large numbers of manual workers have access to canteens. Actual surveys of meals supplied at canteens operated by a well-known catering firm show that in the autumn of 1946 meals and snacks served daily provided from 530 to 1,570 calories per head. The canteens in which the surveys were carried out were for workers ranging in activity from sedentary to heavy work. It would therefore seem from this finding that the heavy worker is able to get up to 1,500 calories daily at his canteen, thus filling the gap for the man requiring 3,500 calories. If the worker's diet were still

It is very probable therefore, that the numbers who require more than 3,500 calories a day are few and between.

Miner—The energy requirements of the miner are probably about 3,500 calories on the average. He is entitled to special rations of 12 oz (340 g) of cheese, 10d worth of meat, and six BUs. These alone provide about 700 calories, leaving 500 calories to be made up from unrationed foods, which as Table III shows should present little difficulty. He would require to eat $1\frac{1}{2}$ lb (680 g) of potatoes a day, but he need not change any points into BUs. Canteen facilities would, as in other instances, make it easy for him to secure his requirements. Those miners who require, say, 4,000 calories daily, and there may well be some, would obviously have less difficulty than the ordinary manual worker in attaining this or even a higher level of intake.

Hospital Patient—There is no need to consider the patient suffering from complaints, such as peptic ulcer and diabetes, for which there are priority allowances. It will only be necessary to pay attention to those patients who are all relatively well, as in most hospitals these constitute the majority and require a fairly substantial diet. Broadly speaking, the rations of such a patient are the same as the domestic rations plus certain extras which the hospital

TABLE III—Bridging the Gaps between Rations and Requirements

	Adolescent		Normal Male		Expectant Mother		Manual Worker (Male)		Miner		Hospital Patient

The rations of the expectant mother include her special allowances of meat, milk, eggs and bread; the rations of the miner and manual worker (male) do not include the special allowances of cheese and meat which are listed separately (see numbers 8 and 9) in Table III.

insufficient for his needs he would have to have recourse to the means indicated in Table III—change of points to BUs, etc. The British Restaurant or other eating-places could be used if a canteen were not available at the place of work, but those who are out of reach of any sort of extra meals are not so well placed to fill the gap between rations and requirements. Certain classes of heavy workers, such as farm workers, quarrymen, and lumbermen, are allowed an extra 12 oz (340 g) of cheese and six BUs weekly, providing about 630 calories a day, thus leaving about 570 to be obtained from unrationed foods. Table III shows that they should be able easily to get about 1,260 calories, but they would need to eat 2 lb (908 g) of potatoes daily. If a workman required substantially more than 3,500 calories he would, unless he were able to extract a substantial amount from the family pool, have to change more of his points into BUs in order to reach, say, the 4,000-calorie goal. If he changed his remaining two points into BUs he would get an additional 100 calories, which would give him altogether 3 960 (2,300 + 1,560 + 100) (Table III). Knowledge of the energetic expenditure of the modern industrial worker is scanty. The only figures we possess date from before or shortly after the 1914-18 war. Since that time workmen's tools and conditions in industry generally have so altered that work is becoming less and less laborious, thus demanding less energy expenditure.

patient gets. These extras amount approximately to the following: milk, 3 pints (1 7 l), dried milk, 7 oz (200 g), fats, 2 oz (57 g), dried eggs, 0.3 oz (8.5 g) weekly. These extras yield about 330 calories a day, and together with the amounts derivable from the ordinary rations make up a total of nearly 2,200 calories. The requirements for the average patient of the above type is probably about 2,500 calories, so that he has a gap of 300 calories, which can easily be filled in by unrationed foods (Table III). Even if there were no spare rations from patients who are on light diets there should be little difficulty in making up a diet to this level. In addition, certain other concessions have been made to hospitals—for instance, jellies, soft drinks, starch products, hospitals are also generally well placed to obtain supplies of fish and sometimes offal and poultry, all of which help to ease the burden of catering. The only account that has been taken of these concessions is that the allowance of fish in Table III has been placed at 3 oz (85 g) instead of $1\frac{1}{2}$ oz (42.5 g) a day. Sick people are notoriously difficult to cater for, and the longer they remain in hospital the more exacting they become. In hospitals where the bulk of the patients are relatively well, and few are so ill as to be restricted to light diets, the provision of varied, appetizing, and adequate meals is a task demanding much ingenuity and artistry as well as knowledge of dietetics. In tuberculosis and orthopaedic

hospitals, for instance, the great majority of the patients are on full diet, and there are few, if any, spare rations

Summary

The rations for each important section of the population have been evaluated and compared with the League of Nations scale of requirements. The comparison is summarized above.

In those instances where the yield of nutrients from the rationed foods is less than requirements suggestions are made for meeting the deficit by one or more of the following, having regard to prevailing dietary habits: (a) consumption of unrationed foods, (b) canteen and similar meals, (c) exchange of points into BUs, and (d) the family pool.

In making these suggestions attention has been confined to energy requirements, because experience of wartime diets has shown that, given the full rations, the additional unrationed foods necessary to satisfy energy requirements also provide, or almost provide, a sufficiency of all important nutrients.

It has been found that the filling of the gap should present no great difficulty for the great mass of the population who can, if necessary, supplement their rations from (b) and (c) sources, but it may not be easy for adolescent and other males whose requirements are above the average for their class and who are not entitled to special rations and cannot supplement their diet from sources (b), (c), or (d).

A SIMPLE FORMULA FOR THE CALCULATION OF ATMOSPHERIC DRYNESS

BY

R. L. WYNNE, MB, MRCS, DA

Anaesthetist Birkenhead General Hospital

The following case, though an extreme one which occurred during the stresses of wartime, illustrates the fact that in British practice too little attention is usually devoted to the atmospheric conditions of operating theatres. They often get too hot, not only in summer-time but also in winter, when central heating is operated with more enthusiasm than discretion, and their humidity tends to rise with the addition of steam from sterilizers. The control of these conditions should be especially cared for in a place where the working staff are expected to maintain a high standard of mental alertness, and where the heat-regulating functions of the patient, like all the functions of his nervous system, are set in partial abeyance by anaesthesia.

Case Report

During the war an underground hospital was built with a view to its use in emergency. An anaesthetist was asked to comment on the suitability of the operating theatre it contained. The ventilation was far from efficient and when the sterilizers were in operation and several people were working in the theatre the atmosphere became extremely hot and moist. The anaesthetist in his report pointed out that patients when anaesthetized tended to become poikilothermic, and that in such an atmosphere complications—for example ether convulsions due to the breakdown of thermal equilibrium—would be likely. This report was not taken very seriously and later the anaesthetist was required in circumstances which admitted of no denial to set to work in this operating theatre. Some 30 cases were operated on successfully. One day a man was brought in for operation on bilateral inguinal herniae.

He was a ship steward aged 31. His temperature was normal, pulse 60 respirations 18, and blood pressure 120/80. He had no history of previous illness. He was a perfectly healthy man except for the herniae which he wished to have operated on. After preliminary medication with omnopon and scopolamine, anaesthesia was induced by 0.75 g of pentothal, and continued by 6 litres per minute of gas and oxygen (the latter in 25% concentration) with ether. After half an hour he was seen to be sweating profusely, as indeed everyone in the theatre was, and the volume of his respiration started to increase. The thermometer hanging on the wall registered 81° F (27.2° C)

and the atmosphere was very moist. The total volume of gases delivered to the mask was increased to 12 litres per minute, still in 25% concentration, and after 45 minutes ether was discontinued. After 55 minutes the patient was red and sweating, the hyperpnoea was no better, and his pulse had risen to 126. The hernia on the right side was finished in 60 minutes, and at the request of the anaesthetist the operation on the other side was abandoned. On the patient's return to the ward his temperature was found to be 106° F (41.1° C) and his pulse 160. Cooling treatment was given, and oxygen and CO₂ administered. Within an hour he was dead. At necropsy no appearances other than those of heat-stroke were found. The underground theatre was not thereafter used.

Noteworthy features of this case are: (1) it was a case of pure heat-stroke, unaccompanied by any sign of convulsions, (2) there was no question of sweating being impaired by atropine, (3) there was no question of anoxic anoxia, (4) if the hyperpnoea led to any serious degree of CO deficiency, this was combated by the administration of CO in mixture, (5) there was no question of sepsis or pre-existing fever.

Calculation of Drying Capacity of Air

Moisture in the atmosphere is usually estimated by means of the "wet- and dry-bulb thermometers," which when exposed to an atmosphere not entirely saturated with water vapour will show readings differing by a certain number of degrees. The lower temperature of the wet bulb is caused by abstraction of heat in the process of evaporation of some of the water covering it. For scientifically accurate results the thermometers must be subjected to considerable air movement, and in America the "sling-psychrometer" is used for this purpose. The instrument is whirled through the air at a considerable velocity on the end of a sling. In England the usual open-air method is to expose the thermometers in a Stevenson screen, by which they meet with a slighter movement of the air, and in indoor conditions the thermometers are simply hung in a room in comparative calm.

The partial pressure of the water vapour contained in the air may be expressed in millibars by the empirical formula

$$P = S^w - f \Delta$$

where P is the actual pressure in millibars of water vapour in the observed conditions, S^w the pressure at saturation point at the temperature of the wet bulb, Δ the difference in Fahrenheit readings between the two thermometers, otherwise termed the "depression," and f is a constant which depends on the pressure and velocity of the air passing over the bulbs. When using the sling psychrometer the value of this constant is 0.367, in England for use with the Stevenson screen, the Air Ministry has adopted the value of 0.444. In the calm and not precise conditions of thermometers suspended in indoor air the round value of 1/2 is probably accurate enough.

The values of the partial pressure of water vapour at saturated conditions at various temperatures are well known.

The continuous line follows the curve, the broken line indicates the curve $y = \frac{1}{10}x^2 - \frac{1}{2}x + 12$

and have been plotted in the form of a curve in the accompanying figure. When these values are expressed in degrees Fahrenheit and millibars, it will be seen that the curve of saturation pressures between the temperatures 30° and 90° has a remarkable similarity to the parabola

$$y = \frac{1}{100} x^2 - \frac{1}{2} x + 12$$

The greatest error introduced by using this equation occurs in the neighbourhood of 76° F at which the true value of the saturation pressure is 30.66 millibars, and the value calculated by the equation is 31.76, an error of a trifle over 1 millibar. Elsewhere this error decreases, and at three points over the indicated range the calculated value coincides with the true value.

Using the equation, one may write

$$S^w = \frac{1}{100} W^2 - \frac{1}{2} W + 12$$

where W is the temperature Fahrenheit of the wet bulb. Hence, from the formula $P = S^w - f \Delta$, and taking $f = \frac{1}{2}$,

$$P = \frac{1}{100} W^2 - \frac{1}{2} W + 12 - \frac{1}{2} \Delta$$

But $\Delta = D - W$, where D is the temperature Fahrenheit of the dry bulb, and the formula thus becomes

$$P = \frac{1}{100} W^2 - \frac{1}{2} D + 12$$

Partial saturation of the atmosphere by water vapour is usually expressed in terms of "relative humidity," which is the ratio of its actual vapour pressure to the pressure which would be attained by saturation at the same temperature, expressed as a percentage. Using the term H for relative humidity, and S^d to express the saturation pressure at the temperature of the dry bulb, one may thus write

$$H = 100 \frac{P}{S^d} = 100 \frac{\frac{1}{100} W^2 - (\frac{1}{2} D - 12)}{\frac{1}{100} D^2 - (\frac{1}{2} D - 12)}$$

Thus, as may be seen, to estimate the relative humidity the only figures required are the squares of the thermometer readings, each divided by 100 and diminished by half the dry-bulb reading less 12. For example, if the dry bulb reads 60° F and the wet bulb 55° F, half the dry-bulb reading less 12 will equal 18, and subtracting from each of the squares the relative humidity is found to be

$$100 \frac{30.25 - 18}{36.00 - 18} = 68\%$$

If the dry bulb reads 71° F and the wet bulb 67° F, the relative humidity is found to be

$$100 \frac{44.89 - 23.5}{50.41 - 23.5} = 79\%$$

The relative humidity is, however, not a very valuable figure if, as is usually the case, it is desired to estimate the capacity of the air to absorb moisture, since the total capacity of the air varies greatly at different temperatures, and at low temperatures is so small that even a small relative humidity does not indicate a great residual ability to absorb moisture.

For practical purposes the drying capacity of the air is better expressed as the "saturation deficiency," or the number of millibars by which the partial pressure of the water vapour actually present falls short of the saturation pressure at the same temperature. This figure, expressed in terms of the equation, becomes

$$\begin{aligned} S^d - P &= (\frac{1}{100} D^2 - \frac{1}{2} D + 12) - (\frac{1}{100} W^2 - \frac{1}{2} D + 12) \\ &= \frac{1}{100} (D^2 - W^2) \\ &= \frac{1}{100} (D + W) (D - W) \end{aligned}$$

The above expression, which might be called the "index of drying power" of the air (and approximates the true value of the saturation deficiency in millibars), thus becomes a figure which can rapidly and easily be calculated direct from the thermometer readings without the help of tables, should these not be available. For example, the thermo-

meters might show readings of 50° F and 45° F. The sum by the difference, and dividing by 100, the index of drying power is found to be 4.75. In another place they might show 75° F and 68° F, by the same calculation the index is found to be 10.01. In the second case, though the depression of the wet bulb is only 2° F greater, the air has more than twice the drying power.

Discussion

Wet- and dry-bulb thermometers are rarely seen in operating theatres, but I would suggest that were they more commonly used, and the proposed simple calculation of the index of drying power carried out from time to time in conjunction with readings of the dry bulb, the results might in many cases prove illuminating. The importance of the wet-bulb temperature was long ago pointed out by Haldane (1905), who found that, whatever the dry-bulb temperature, heat-regulation would begin to break down when the wet-bulb temperature rose above 88° F (31.1° C). Probably 70° F (21.1° C) should be regarded as the upper limit of safety in an operating theatre.

The hazards of hot and moist atmospheres have been emphasized, but those at the other extreme are scarcely less important. Cold surroundings will produce or aggravate surgical shock, and a very dry atmosphere will facilitate the production of high static electrical potentials with a corresponding risk of explosion of inflammable vapours. Such dryness is but rarely encountered in Great Britain but I have on at least one occasion heard the crackle of a static discharge in a theatre when a dry blanket was quickly pulled away from a trolley.

The formula ($P = S^w - f \Delta$) and the figures for partial pressures are taken from the Air Ministry Hygrometric Tables, M.O. 265 (1940), published by H.M. Stationery Office, and I have to thank the Director of Bidston Observatory for drawing my attention to that useful publication.

Summary

It is pointed out that an assessment of the drying capacity of the air can be made by a no more complicated procedure than finding the product of the sum and difference of the wet and dry-bulb readings.

It is suggested that the atmosphere of operating theatres should be more rigorously investigated and controlled.

TRAUMATIC URAEMIA: RECOVERY

BY

J. C. SCOTT, MS, FRCS

AND

C. G. ROB, FRCS

(From the Radcliffe Infirmary, Oxford)

Below is reported a case in which a penetrating wound of the right thigh with division of the femoral artery and vein, without any apparent injury to the abdomen or left leg, led to an ischaemia of both legs. This was followed by a great increase of blood urea and other signs suggesting the onset of traumatic uraemia. After splanchnic block the blood urea fell and the general condition improved sufficiently to permit amputation of both legs. Following amputation progress was uninterrupted. Trueta and others (1946) suggest that splanchnic block should prove of value in

traumatic uraemia. The result in this case seems to give some support to that suggestion.

Case Report

The patient, an agricultural worker aged 65, was found lying in a pool of blood after his horse and cart had returned to the farm without him. As he was alone, no details of the accident were available. It seems likely that the cart passed over his right leg.

He was admitted on July 5, 1946, about two hours after the injury, in *extremis* with no ascertainable pulse or blood pressure. The only visible injury was a small puncture wound of the inner side of the right thigh. There was no bleeding from this wound on admission. X-ray examination showed no bone injury. The transfusion of 5 pints (2.8 l) of plasma and 1 pint (0.57 l) of blood (group B) raised the blood pressure to 110/60. No other immediate treatment was given.

On the morning after admission it was obvious that there was no circulation or sensation in the right leg below the knee. The left foot in which the circulation had appeared satisfactory on the previous evening now showed cyanosis of the toes. The popliteal pulse was palpable but neither the posterior tibial nor the dorsalis pedis could be felt. There was no evidence of injury to this leg. The transfusion cannula had been inserted in the left ankle. Routine treatment for vascular injury was carried out—that is, heat to trunk, exposure of limbs, no smoking, 1 oz (28 ml) of brandy or whisky four-hourly. In view of impending gangrene of the right leg and the failing circulation of the left leg, exploration of the wound was considered advisable. This was carried out about 22 hours after the injury. There was considerable muscle damage, and the femoral artery and vein were completely divided at the junction of the middle and lower thirds and thrombosed. The wound was excised and closed with drainage after icing with proflavine-sulphathiazole powder. The following day the patient's general condition was poor. He was at times irrational and incontinent. The fluid intake was maintained—102 oz (2.9 l). The output was difficult to assess because of incontinence, but appeared to be lowered—20 oz (0.6 l). The blood pressure rose to 145/80. The general condition was about the same on July 8. The right leg was avascular to the knee, and the left avascular to the level of the ankle. The blood urea was 168 mg per 100 ml, plasma chloride, 525 mg NaCl per 100 ml (90 m equiv/litre), plasma bicarbonate, 56 vols per 100 ml (25 m equiv/litre), plasma protein, total, 5.42 g per 100 ml (albumin 3.52 g). The fluid intake was 84 oz (2.4 l) and the output 49 oz (1.4 l).

In view of these findings splanchnic block was advised, being carried out by Dr MacKay of the department of anaesthetics, 40 ml of 5% "novocain" was injected by the post route under 0.2 g of thiopentone. After the injection the blood pressure dropped 20 points. Investigations on subsequent days were: July 9, blood urea 184 mg per 100 ml, haemoglobin (?) (specimen taken soon after splanchnic block), July 10, 128 mg, 50%, July 11, 96 mg, 42%, July 13, 72 mg, 50%, July 15, 80 mg, 40%, July 19, 50 mg, 62%.

On July 18 the difficulty with regard to measuring fluid output persisted. The general condition of the patient remained about the same. There was general emaciation but otherwise no serious deterioration. Gangrene of both legs was well developed. The right leg was dry, requiring above-knee amputation. There were some blisters on the left leg and mild cellulitis. An above-knee amputation of the right leg was performed and 2 pints (1.1 l) of blood was given. Next day the general condition improved, and he was rational for longer periods. The pulse was 110, blood pressure 130/80, haemoglobin 62%, blood urea 50 mg per 100 ml. On the 24th the haemoglobin was 64% and the blood urea 28 mg per 100 ml. A below-knee amputation of the left leg was made on the 25th and 2 pints (1.1 l) of blood were given. On July 31 the haemoglobin was 84%.

Since the second amputation the progress has been uneventful. Incontinence has completely ceased and the patient is rational. He eats and sleeps well, and the stumps are practically healed.

MASSIVE PENICILLIN DOSES IN GENERAL PRACTICE

BY

D P WHEATLEY, MB, MRCS

In the *Journal* of Nov. 30, 1946 (p. 842), it was stated that the writer knew of no comparative data for larger doses of penicillin than 100,000 units, or of such doses at infrequent intervals. I venture, therefore, to record a few minor conditions treated by this method in general practice.

Case Reports

Case 1—Mrs S, aged 45, had been troubled for some time with recurrent and severe boils in the nose. The usual duration of one of these was one to two weeks. Two days before I saw her one had started, and she consulted me as she was particularly anxious to go away for a week end two days later. She had a full blown and very painful boil just inside her nose. I gave her 200,000 units of penicillin by intramuscular injection, this being repeated the following day. The next day the boil had almost completely subsided and gave her no further trouble.

Case 2—Mr P, aged 32, had had a large whitlow on the third finger of his left hand for three days. It was already discharging but the whole finger was grossly reddened and swollen. In addition, he felt unwell, and an eruption of small furuncles had broken out all over his body. He was given 200,000 units of penicillin. The next day he felt very well in himself although there was no significant change in the whitlow. A further 200,000 units was administered, and the following day the whitlow was discharging profusely, most of the swelling had subsided and the furuncles had almost disappeared. Two further injections of 200,000 units were given, and he was able to return to work one week after the beginning of the infection. He was seen a week later, when the finger was practically healed.

Case 3—Mr S, aged 42, had had a severe carbuncle just below his left elbow for three days, there was much inflammation, and several heads were beginning to form. He felt unwell, and had a slight temperature. He was given 200,000 units of penicillin. The next day he felt much better, his temperature had fallen and the heads of the carbuncle had increased in size and were already discharging. A further dose was given and the next day the lesion was discharging profusely, much of the inflammation had subsided and the patient was later able to express the main core of the carbuncle. Two further injections were given, and a week later (ten days from its onset) the lesion had completely subsided. No local treatment was given.

Case 4—Master P, aged 5, had had a purulent conjunctivitis gradually getting worse over a period of one week. When seen his left eye was completely closed, much swollen, and a purulent exudate oozed from under the lids. He was given 50,000 units of penicillin. The next day he was able to open the eye and much of the swelling had gone down, although there was still a purulent discharge. Two further doses of 50,000 units were given on the following two days. The eye was then perfectly normal, except for one or two small tags of crusted exudate on the lashes.

Case 5—Miss F, aged 12, had a large sty on the lower lid of her left eye. This had been treated with ung. hyd. oxid. flav., and had all but cleared up when it broke out again. There was a similar occurrence after penicillin ointment. In all she had suffered from the sty for a period of two weeks. A single injection of 200,000 units of penicillin was given, but she declined a further injection, as she did not relish the procedure. As it happened, this was not necessary for by the next day the condition had cleared up.

Case 6—Mr G, aged 52, developed a carbuncle on his neck following an eruption of boils, he had never had either before. When first seen the carbuncle was of ten days' duration. He had several small healed boils, and another carbuncle three days old, was forming on his right thigh so far without a head. He was given four daily injections of 200,000 units each of the highly purified white crystalline penicillin. At the end

this time only a scar remained at the site of the carbuncle on his neck, the one on his thigh had completely aborted

Case 7—Mr K, aged 41, had had a carbuncle on his right forearm for five days. He complained of pain up the arm and in the axilla. He was anxious to return to work as soon as possible, and 200 000 units of penicillin was given twice daily for three days and a single dose on the fourth day. By this time the swelling had nearly subsided and the carbuncle was discharging freely.

Comment

The successful treatment of the above cases would seem to justify the use of large doses of penicillin at infrequent intervals, such as can conveniently be carried out in general practice. The particular dosage was chosen on the grounds of economy, larger doses might be even more effective and might possibly be of use in more serious conditions. In Cases 3, 6, and 7 the carbuncles cleared up in about five days and the patients were fit for work within a week, indeed, one patient continued working, though against advice, during treatment. This is an important consideration when the cost of the treatment is taken into account.

The introduction of the more highly purified white crystalline penicillin will probably greatly increase the value of this form of treatment.

Summary

Seven cases of minor conditions commonly met with in general practice yet which had responded poorly to routine treatment, have been described. All responded strikingly to large daily injections of penicillin. In each case it was considered that there was a clear indication for this form of therapy, and in none was any local treatment given after starting penicillin therapy. It is of interest to note that the one patient who was given injections twice daily did no better than the others. In the few cases so far treated by this method no failure has been observed.

Medical Memoranda

A Case of Thrombosis of the Abdominal Aorta

The following case of thrombus formation on an atheromatous ulcer of the abdominal aorta immediately above the bifurcation of the common iliac arteries is thought worthy of record because of the disparity between the gross pathology and the symptoms produced. A remarkable feature was that in spite of a massive arterial occlusion no pain was experienced. Boyd (*Textbook of Pathology* 4th ed, 1943) states that thrombus formation on an atheromatous ulcer of the aorta occurs much less frequently than might be expected.

CASE RECORD

A man aged 47 was admitted to the Falkirk Royal Infirmary complaining of numbness and coldness of both lower limbs of three days' duration. Seven days previously, while climbing a steep hill, he was seized with a pain in the left praecordium extending down the left arm to the wrist, and a feeling as if his left leg was swelling and about to burst. After resting for half an hour he continued to climb the hill although the rest had not relieved the pain. On reaching the top he broke out in a cold clammy sweat and felt as if both legs were swelling to bursting point. His legs would no longer support him and he had to sit down and was later taken home in a taxi. In bed apart from his legs and some residual praecordial pain he had no complaint. The legs were normal in colour and muscle power was normal. The next day the praecordial pain and the numbness in his legs disappeared. On the third and fourth days he had no complaint whatsoever although he remained in bed. On the fifth day he suddenly broke out in a cold clammy sweat and his right leg became numb and cold from the sole of the foot to the hip. The leg became discoloured and muscle power was lost. There was no pain. Later that day his left leg from the sole of the foot to the knee became gradually numb and cold. Again pain was conspicuous by its absence. He also became incontinent of urine and faeces. Two days later he was admitted to the infirmary. On two occasions two months previously he had experienced slight pain in the calves of both legs on climbing a hill. This passed off quickly after rest.

On admission he was seen to be a well built man whose face was somewhat congested and who had a fair degree of clubbing of the fingers. The right leg showed marked discoloration and was cold and pulseless. The line of demarcation was about 5 cm below the inguinal ligament. There was complete loss of sensation and muscle power. The left leg was similarly affected immediately below the knee joint. The heart was irregular in rhythm and force and the heart sounds were of very poor quality. The blood pressure was 110/80. Examination revealed no abnormality of any of the other systems. The Wassermann reaction was negative. He died some nine hours after admission.

Post-mortem Examination—There was an atheromatous ulcer about 2 cm in diameter on the anterior wall of the aorta about 4 cm above the bifurcation of the common iliac vessels. It had involved the intima and media and was on the point of rupturing through the adventitia. There was a large adherent thrombus over the site of the ulcer which extended down both iliac vessels to their bifurcation and involved 2 cm of the left internal iliac. There was also a great deal of patchy calcification over the area covered by the thrombus. Proximal to this the aorta appeared normal, as did the other arteries. The heart was dilated and showed a marked fibrosis of the myocardium, the wall of the right ventricle being parchment-like. The right ventricle showed an old coronary thrombosis. An interesting feature was the complete absence of rigor mortis of the affected limbs.

I am indebted to Dr T Kay MacLachlan, Consultant Physician, Falkirk Royal Infirmary, for permission to publish this case.

A Case of Dissecting Aortic Aneurysm Diagnosed Clinically

In view of the infrequency of the clinical diagnosis of cases of dissecting aortic aneurysm I am grateful for an opportunity to publish this case. Dissecting aortic aneurysms are comparatively rare lesions, and particularly so in women, the incidence in men to women is three to one (Paul White, 1946).

CASE REPORT

A well nourished obese woman aged 40 was admitted to hospital at midnight on Jan 24 1947. The patient was in an acute state of shock. She was ashen grey, clammy, and perspiring. Her pulse rate was about 100, irregular, and of very poor volume. It was impossible to record the blood pressure in the right arm, but the systolic pressure in the left arm was 70 mm. She was very restless but was able to give her history fairly well. This was as follows. At 12 noon on Jan 24, suddenly after a very heavy morning's work, she experienced a "terrible pain" between the scapulae and radiating slightly towards the back of the neck, she fell into a chair. She vomited twice and when seen at 2.30 p.m. the same day by her husband she was acutely shocked and "helpless" she coughed a very small amount of bright-red blood. The only relevant past history was that she had had a cough for the last three weeks, but otherwise was well and active. She had five children alive in the case of the youngest child labour was induced at the seventh month for "kidney trouble and blood pressure".

Clinically it was impossible to determine the size of the heart, and the heart sounds were almost inaudible. There were no abnormal physical signs in the lungs, abdomen, or central nervous system. The fundi showed arteriosclerotic changes, and no exudates were seen. It appeared that this patient had had an acute circulatory catastrophe. Coronary thrombosis seemed a possible alternative diagnosis, but the site and nature of the pain in the back and its maximum intensity at the onset were both points in favour of a dissecting aneurysm. She died at 11 a.m. on Jan 25.

Post-mortem Findings—The pericardium was considerably thickened and there was a large haemopericardium. The weight of the heart was 25 oz (0.7 kg), and the left ventricle was hypertrophied. There was a break in continuity of the intima of the aorta in the transverse portion opposite the origin of the innominate artery. This was some 1/2 in (1.25 cm) long in the longitudinal direction. This break was continuous with a cavity in the wall of the aorta and dissected about one half the circumference of the aorta. The cavity contained blood clot, and extended down to the aortic valves. The coronary arteries were fairly healthy. There was extensive atheroma of the intima of the aorta more marked distally. The left kidney was small, with the capsule adherent and its surface was slightly granular.

I wish to thank Dr E H Brindle for permission to report the case, and Dr J R Mackenzie for much helpful criticism.

"A VERY PRACTICAL SCIENCE"

Fundamentals of Immunology By W C Boyd, Ph D Revised reprint (Pp 446, illustrated 33s) London Staples Press, Ltd

Immunology is indeed, as Prof Boyd writes in his first chapter, 'a very practical science, concerned with methods of preventing disease or influencing its course, but it touches clinical medicine at unrelated points. In a few instances prophylactic inoculation is useful, antisera, of which we once hoped so much, are effective in still fewer, various serological reactions are used in diagnosis. Nevertheless we learn from the Rh reactions that what may now seem merely test-tube serology may at some time become the key to the aetiology and treatment of a serious disease. Until more is known of the physical chemistry of proteins and of the nature of inter-molecular forces many events in serology will remain disconnected.'

In teaching students this complicated subject, any detail of which may prove to be of vital importance, Prof Boyd considers that the chief emphasis should be on serology, 'if by that we mean the science which studies the fundamental mechanism of immunological reactions and their theoretical foundations.' He recounts fully our present knowledge of antibodies, the relation of the specificity of antigens to structure, and the nature of antigen-antibody reactions. Some of the more advanced material is printed in small type to distinguish it from that 'which the beginner can and should be expected to master,' but even the remainder is more than any beginner could digest. Prof Boyd, who does not oversimplify his subject, modestly hopes that the book will be of some use to the professional immunologist. He might have claimed much more: the book should be of the greatest value to any who are engaged in or intend to take up immunology as a special study. He presents the theoretical aspects of the subject fully and clearly and has co-ordinated much material that previously lay scattered about the literature. The book is written in his usual agreeable style.

NUTRITION

Food and Health. An Introduction to the Science of Nutrition By A Barbara Callow, MSc, MSc Third edition (Pp 184, illustrated 6s) Oxford The Clarendon Press 1946

Food Control and Nutrition Surveys Malabar and S Kanara By K G Sivaswamy, et al (Pp 225 Rs 4) Madras Servinda Kerala Relief Centre, Royapettah

Inadequate Diets Deaths and Diseases and a Food Plan for Madras By K G Sivaswamy, et al (Pp 84 Rs 2) Madras Servants of India Society, Royapettah

The first of these books is an introduction to the science of nutrition designed for students and the general reader and is particularly relevant in these days of world food shortage. The previous edition has been largely rewritten. In addition to the facts usually found in a book on nutrition there is useful information on choice of foods, special diets, the effect of cooking on nutritive value, and very extensive food tables. As a short survey for the general reader this book is strongly recommended.

The authors of the two books from India discuss the appalling malnutrition and morbidity in some of the States—where indeed in certain areas the death rate is higher than the birth rate. The books are well documented and contain precise suggestions for improving the health and diet of the masses—such as the growing of more food, the subsidizing of agriculture and a basic diet for the poor, the control of food, rents, and wages and an increase in the purchasing power of the poor.

BASAL METABOLISM

Hypometabolism. A Clinical Study of 308 Consecutive Cases By Esben Kirk, MD, and Sven Ancher Kvorning, MD (Pp 84 Dan Cr 7.25 or 7s 6d) Copenhagen Einar Munksgaard London Heinemann Medical Books 1946

The authors have studied the basal metabolism of the majority of patients admitted to the medical department of the Holstebro District Hospital in Denmark during the years 1940, 1941, and 1942. They have not recorded the number of patients investi-

gated, but in 308 cases the basal metabolic rate was found to be below 88% of normal. An analysis of the findings from the clinical examination of these 308 patients is the subject matter of this monograph. In 30 myxoedema or cachexia strumipriva was the cause of their hypometabolism, in 44 there was reduced physical activity, the patient often being bed ridden, in 41 the intake of food was greatly reduced. Low basal metabolism is expected in these three groups.

Of greater interest is the number of women with 'hypogonadism' in the series, these, mainly patients whose ovaries had been removed or who suffered from oligomenorrhoea constituted 21% of the total. The mechanism of their reduced metabolism is uncertain, but secondary hypothyroidism is a possibility. In the largest group—109 patients—21 were considered to be healthy, while the remainder had various ailments not usually thought to affect the metabolism. The metabolic rates of a random sample of this group conformed to the left-hand section of an ideal distribution curve the right-hand section of which was obtained from control cases. The authors believe these had a 'physiological hypometabolism,' and suggest that some healthy individuals may have basal metabolic rates considerably below 'normal.'

R BODLEY SCOTT

X RAYS IN UROLOGY

Urologic Roentgenology By Miley B Wesson, MD Second edition, thoroughly revised (Pp 260, 258 engravings 27s 6d) London Henry Kimpton 1946

Although no great advance in x-ray examination of the urinary tract has been made since the previous edition of this book technique has steadily improved. With the help of the radiologist it is now possible to diagnose lesions formerly discovered only at operation—a striking example being that comparatively rare lesion, renal aneurysm. The author has replaced many of the old illustrations with new, rewritten most of the text, and included the latest references. Comparison of the old plates with the new reveals the progress in this branch of medicine. This is certainly the finest collection of urological x-ray illustrations that have appeared in any book and the text is lucid and concise.

Our only criticism is that the author is occasionally rather dogmatic. This is particularly noticeable in the chapter on hydronephrosis, from which the inexperienced reader may easily conclude that all forms of hydronephrosis are caused by obstruction and that the nature of the obstruction can usually be discovered, whereas in many cases the precise aetiology remains obscure. However, as the author points out in his preface, dogmatism in a book of this type has certain advantages. His aim is 'not to supply a treatise but to provide a vade mecum which will help the newcomer in urologic roentgenology to interpret his pictures.' Dr Wesson admirably achieves this end. His book can be highly recommended not only to the general reader but to specialists in this particular subject.

APHORISMS ON CANCER

Quelques Verites Premieres (ou soi disant telles) sur le Cancer By René Huguenin Preface by M Gustave Roussy (Pp 140 200 francs) Paris Masson et Cie 1946

This book on basic truths about cancer is one of a series designed to present the fundamental truths of medicine, so far as they are at present recognized, in the form of aphorisms reminding practitioners of rules of practice which they should not lightly transgress and indicating to students what is of capital importance in their studies. The form of presentation is of doubtful value, nevertheless Huguenin writes with the authority of wide experience, and much of what he says is stimulating. As it stands, the book is an interesting supplement to orthodox textbooks.

After a general discussion of the nature and origin of cancer there is a section on the diagnosis of the individual varieties. A chapter on the habits of growth and spread of cancer leads to a discussion of therapeutic measures, and a final chapter is devoted to cancer as a social problem. The emphasis of the book is on early exact, and complete diagnosis and on judicious choice of treatment. Huguenin insists that in its early stages cancer presents no distinctive clinical signs or symptoms, the orthodox textbook descriptions apply

to advanced stages and are commonly useless or even misleading in the quest for early diagnosis. There is no single method of treatment appropriate to all kinds of cancer. Correct choice of treatment, upon which the patient's life depends, requires precise knowledge of the type of the tumour, its extent, its usual habits of growth and dissemination, and of concomitant lesions. A diagnosis which is sufficiently early and exact can often be established only by histological examination, and he is a warm advocate of biopsy, and especially of per-operative biopsy in the theatre, with the surgeon prepared to act promptly on the findings. He discusses the knowledge and skill required from surgeon and pathologist to ensure reliable results and the subsequent procedure to minimize the risks of biopsy. Huguenin is impressed by the importance of general and local conditions favouring or impeding the growth and spread of cancers, though dearth of knowledge of these factors precludes at present, the influence on therapeutics which they may exert in the future. The isolation of French medicine during the war no doubt accounts for the cursory reference to treatment of carcinoma of the prostate by oestrogens, and the author seems to write without personal acquaintance with the method. Personal experience and reflection inform the rest of the book.

L. FOULDS

ACTION OF DIGITALIS

La Digitale et Les Strophanthines Pharmacodynamie-Thérapiutique. By D. Danielopolu (Pp 206 illustrated. No price given) Paris: Masson et Cie 1946

It is interesting to read the opinions of an author from Bucharest on such a subject as the action of digitalis, we learn how different his standpoint is from ours. He does not regard as important the increased force of ventricular contraction that digitalis causes, nor does he discuss its action in depressing conduction in the bundle of His; he says nothing of digitalis causing a reduction in the number of impulses reaching the ventricle from a fibrillating auricle or of an extra-cardiac action of digitalis whereby increased venous tone reduces the venous pressure at the entrance to the right auricle.

Danielopolu is chiefly concerned with the relation between the digitalis glycosides and acetylcholine and he shows from a series of experiments that in the presence of strophanthin the effect of acetylcholine and of vagal stimulation is strikingly increased. This augmentation of the action of acetylcholine is seen in both cardiac and many other tissues in the presence of, for example strophanthin in concentrations which it must be said are rather high. Though increased vagal action slows the heart few to-day consider that vagal slowing is closely connected with the beneficial action of digitalis. However, we tend to overlook the observations made by Lewis, Drury and Iliescu which seemed to puzzle those who made them that when atropine is injected into the vein of a fully digitalized patient with fibrillation there is a sudden large acceleration in the ventricular rate from 70 or 80 to 160 or even 180. There may therefore be more truth in Danielopolu's viewpoint than we usually admit. Increased acetylcholine action may, however, affect more than the heart rate for it is becoming apparent that all substances which prolong the refractory period and diminish conduction in cardiac muscle are acetylcholine antagonists and that acetylcholine not merely inhibits the heart but is concerned in the transmission of the contractile process and perhaps in the contractile process itself. If that should prove correct the importance of the relation between digitalis glycosides and acetylcholine will be firmly established.

J. H. BURN

Volume LXV of the *Transactions of the Ophthalmological Society of the United Kingdom* for the session 1945 has been published by A. Churchill at 40s. It comprises full reports of the proceedings of that society at the annual congress held in London in April 1945; it also includes the Dove lecture and other papers read before the Oxford Ophthalmological Congress at its thirty-first annual meeting. Among the main subjects dealt with in this volume are ocular sequelae of head injuries, plastic repair of the lids, traumatic detachment of the retina, the sympathizing eye, compression and invasion of the optic nerves and chiasma by neighbouring gliomas (Geoffrey Jefferson's Dove lecture), injuries to the eyeball and retrobulbar neuritis (paper by L. E. Werner read to the Irish Ophthalmological Society).

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Allergy in Theory and Practice By R. A. Cooke, M.D., Sc.D. F.A.C.P., et al. (Pp 572 40s) Philadelphia and London: W. B. Saunders 1947

The authors discuss allergy in all its aspects and intend the book for general practitioners as well as specialists.

A Plan for Science By the Science Advisory Committee of the Communist Party (Pp 32 6d) Watford: Farleigh Press 1947

A memorandum on the application of science to industrial and social problems.

Diseases of the Retina By H. Elwyn, M.D. (Pp 587 45s) London: Churchill 1946

The author discusses disturbances in circulation, vascular malformations, degenerative and inflammatory diseases, tumours, retinal detachment, developmental abnormalities, and radiation injuries.

Le Probleme Biologique du Cancer By J. Delarue (Pp 200 300 francs) Paris: Masson 1947

The author considers the aetiology of cancer, experimental evidence, the pathology and clinical aspects and the treatment of cancer.

Le Chirurgien en presence de l'Etat Diabétique By J. Bréhant (Pp 541 1,200 francs) Paris: Masson 1946

Includes discussion on surgical procedures for diabetic patients, surgical complications of diabetes, surgical treatment of diabetes and traumatic diabetes.

L'Epilepsie Chronique By P. Hartenberg (Pp 160 240 francs) Paris: Masson 1946

A monograph on the aetiology and symptomatology of idiopathic epilepsy.

Le Probleme des Tuberculoses Atypiques By R. Burnand et al. (Pp 435 760 francs) Paris: Masson 1946

A collection of studies on atypical tuberculosis, including tuberculosis of the skin and the lungs, and discussion of the anatomy, pathology, and bacteriology.

Le Diabete et sa Pathogenese By L. Ambard (Pp 162 240 francs) Paris: Masson 1946

A monograph on the pathogenesis, symptomatology, and treatment of diabetes.

Tuberculosis in Newfoundland By T. O. Garland, M.D., D.P.H. and P. D. Arey Hart, M.D., F.R.C.P. (Pp 58 No price) Newfoundland: Trade Printers and Publishers 1946

A report of an investigation into tuberculosis in Newfoundland, where the disease is particularly widespread.

Anatomy and Physiology By C. F. V. Smout, M.D. 2nd ed. (Pp 470 30s) London: Edward Arnold 1947

This book is planned in accordance with the syllabus of the Chartered Society of Physiotherapy and is intended for students of massage and medical gymnastics.

La Psychologie de L'Intelligence By Jean Piaget (Pp 212 80 francs) Paris: Armand Colin 1947

After discussing intelligence in adaptive processes the author considers its relation to perception, habit, and in the elaboration of thought.

Studies on the Influenza A-Epidemic of January-March, 1941, at Groningen (Holland) By J. A. R. Van Bruggen, M.D. et al. (Pp 79 10s) Leiden: Stenfert Kroese

A monograph on an influenza epidemic in Holland, with photographs, from the Leiden Institute of Preventive Medicine. In English.

A History of the Worcester Royal Infirmary By W. H. McMenemey, M.A. (Pp 356 21s) London: Press Alliance 1947

The author stresses the value of democratic management and local enterprise as well as the need for nation-wide planning.

Heparin in the Treatment of Thrombosis By J. E. Jorpes, M.D. 2nd ed. (Pp 260 18s) Oxford: University Press. Geoffrey Cumberlege 1946

A survey of the chemistry, mode of action, and therapeutic use of heparin for the physiologist and physician.

BREAD RATIONING AND CALORIES

So long as bread was not rationed everyone could get as many calories as he wanted. Not everyone actually got as many calories as he did before the war, partly from dislike of the food that could be bought, partly from a permanent failure to adapt—similar to the temporary failure shown by McCance and his colleagues¹ in their experimental study of rationing. But one of the objects of rationing bread was to reduce the consumption of grain. If consumption is reduced can people still obtain as many calories as they want? Bransby and Magee (p. 525) set out to answer how males and females of different ages and activities can keep their intake up to the level recommended by the Technical Committee of the League of Nations. They estimate the number of calories supplied by rations—that is, by those foodstuffs of which the supply is restricted by regulations. In some cases the rations by themselves supply all the calories needed. In the case of "normal" males, adolescents, manual workers, and pregnant women there is a gap of 560 to 770 between requirements and the calories supplied by rations and the extra BUs allowed. Bransby and Magee propose that this gap can be closed by calories from 4 sources: (1) Unrationed foods, of which potatoes are the most important, other unrationed foods supplying not more than 200 calories per head per day; (2) Canteen and other meals taken "off the ration"; (3) Exchange of points to BUs, since the average calorie value of points is less than that of the bread for which they can be exchanged; (4) The family pool. The third source could, at most, provide an extra 350 calories per head per day. But to change points to BUs involves the sacrifice of much of the little variety of diet that we can now expect. It would mean giving up baked beans, cereals (including all oat products), dried fruit, and sardines. In practice the exchange ran mainly in the opposite direction, so long as the exchange of BUs for points was allowed. It is unlikely that a family will change points to BUs on any scale so long as it can stave off hunger in any other way.

Between 50 and 60% of school-children are not able to get dinner at school, the possible number is limited by the lack of accommodation. Factories over a certain size must provide canteens, and some smaller factories also do so, but a large proportion of factory workers have no canteen, the number of British Restaurants has been

limited by the difficulty of finding suitable buildings, adolescents may find it difficult to afford meals in canteens. Certainly less than half the school children and manual workers obtain extra rationed food in the form of meals away from home, the rest must get from other sources any extra calories they need. Bransby and Magee suggest that owing to the extensive use of machinery for heavy work the average needs of manual workers may be lower than estimated, but it is just those workers who do heavy work with their own muscles who are the least likely to be able to get meals from canteens. We then have to consider how far the gap can be closed by unrationed foods, of which the most important are potatoes. Here Bransby and Magee seem out of touch with realities. The supply of potatoes for human consumption in 1943-4 was, according to *Food Consumption Levels*² 255 lb per head per year, or 5 lb per week. According to the *Monthly Digest of Statistics* production has not risen by much since then. At present it is difficult to get the 5 lb per head per week, and owing to the frost, the late spring, and flooding we may be short of potatoes not only until the new crop is raised but during the next potato year also. Yet the authors write of the consumption of 10½ lb per week by adolescents, normal males, pregnant women, and miners and of 14 lb a week by other manual workers.

We are left then with the fourth source—the family pool. The average amounts of unrationed foods supply about 400 calories per head. With average consumption of these foods the gap, if no outside meals are eaten, ranges from 160 calories (pregnant women) to 370 (manual workers). On the other hand the rations of children of 1 to 5 years (about 5% of the population) supply some 500 more calories than the children need. The average requirements of men and women over 60 years old cannot exceed the 1,840 calories their rations supply. At ages between 5 and 10 rations are sufficient to meet requirements (1,900 per day) according to the scale used by Bransby and Magee. But Bransby and Wagner³ found that children in this age group in Stockport and Stoke on Trent ate the equivalent of about 2,200 calories. There is no reason to suppose that these children were eating more than they needed, so children of this age group should not contribute to the family pool. School-children of 11 years and upwards also need both their rations and the average amount of unrationed foods in spite of their extra allowances of BUs.

The average number of calories taken by women in middle class was, according to Widdowson and McCance⁴ and Widdowson and Alington,⁵ about 2,150 per day, that rations and an average of unrationed foods would leave them about 100 calories to spare. But many of these women were in sedentary occupation, as a whole women probably need all the calories their rations and the average amount of unrationed foods supply. The groups, therefore, whose requirements are exceeded by the calories supplied by their rations plus the average amount

¹ *Food Consumption Level in the U.S.A. Canada and the United Kingdom* 1944. H.M.S.O. London.
² *British Medical Journal* 1945 2 682.
³ *J. Hyg. Camb.* 1936 36 13.
⁴ *Lancet* 1941, 2 361.

of unrationed foods are children up to 5 years and old people. This surplus would, if it were shared, provide those adolescents, normal males, and manual workers who do not get canteen meals, and make up some 17% of the population, with about 400 calories a day and would close the gap. But this distribution is not possible unless the adults, families with young children, and old people take considerably less than the average amounts of unrationed foods, instead of cutting down their purchases of bread.

However unsatisfactory it may be, the family pool is the solution that is adopted in practice. It is based on the principle of women and children last. On this principle the children of families studied in the surveys made during the depression of the early twenties got less than they needed for normal growth, in the lower income groups the pregnant women, whose diets were studied by McCance, Widdowson, and Verdoe-Roe,⁶ received well under the 2,440 calories their present rations supply, although they were allowed a pint of milk a day by the local authorities the average amount they kept for themselves was only 1/4 pint.

Rationing of bread is an evil in a class apart from that of the rationing of other foods. Our diet may not be so dull as some would make out, but there are not sufficient amounts of appetizing foods nor sufficient variety to induce people to eat more than they need, the results of such surveys as have been published confirm this. Rationing of the main source of calories must reduce the intake below needs unless the supply of other foods is increased, if it is to succeed in one of its objects—the restriction of the consumption of cereals. Another object of bread rationing was to check its use for feeding fowls. This could have been achieved as well or better by restricting the number of hens kept by domestic poultry keepers to the number for which the poultry keeper can obtain rations of balancer meal. As it is, the families that do not need all their rations of bread can give the surplus to their fowls, since the exchange of BUs to points was stopped they no longer have any incentive to refrain from doing so. To take oat products off points at this time of the year is to invite their use for feeding chicks.

It should not be necessary to speculate about the effects of bread rationing. The Ministry of Food has for years conducted a survey of the consumption of food by representative families throughout the country. But on the principle that 'any material collected at the public expense by public servants for the public benefit should on no account be made public, the results are still treated as "confidential," and only a few details have leaked out. Oddly enough, Ministers of Food have preferred to quote estimates of the total amounts of foodstuffs going into 'consumption' and the intake of nutrients based on these, when they have these more useful figures in their Department. It is little use to tell us that the supply per week of fresh and frozen meat is some 32,000 tons, or about 1 oz. per head, when we know by experience that the amounts we actually get are considerably less.

VITAMIN C IN THE SPRING

The ascorbic acid in our diet is usually at its lowest in March. By then the amount in potatoes has fallen to a half or a quarter of the level in new potatoes, and green vegetables have become scarce. The supply of vitamin C rises slightly in April and May as more green vegetables appear, but does not reach high levels before the end of July. This year the vitamin C trough will be deeper and more prolonged, for potatoes are becoming scarce, and owing to the long cold winter green vegetables are very scarce and the spring vegetables will be late. In institutions where special care is taken over the supply and cooking of vegetables the average daily intake of vitamin C falls in ordinary years to about 20 mg during March. Many people get less than 10 mg a day. At present they may find it difficult to get even that, for half a pound of boiled potatoes eaten shortly after cooking will supply no more than 5 or 6 mg.¹

Does this shortage matter? Can the population as a whole live without any impairment of health on 10 mg or less of ascorbic acid a day for some two months, preceded by two months or so in which the supply was little higher? How much ascorbic acid do we need in order to maintain full health? Animals that make their own ascorbic acid have some 0.4–0.5 mg of it in 100 ml of plasma. The concentration in the plasma of guinea-pigs, which depend on their food for their ascorbic acid, rises to this level when they are getting the optimum amount for the healing of wounds. To reach such levels an adult human being needs about 50 mg a day. The highest claims of benefit from such large intakes are those of Campbell and Cook,² who found much more rapid healing after extraction of teeth when large doses of ascorbic acid were given, and those of Hunt³ and other surgeons for the improved healing of wounds. Conclusions about healing after extraction have been criticized on the ground that no allowance was made for the effect of the first extraction or the rate of healing after the second, and it is not certain that the control subjects of operations were strictly comparable. Several experiments with supplements of ascorbic acid provide little evidence of benefit. Bransby and colleagues⁴ reported a slight reduction of the incidence of gingivitis but no other improvement among children taking 50 mg of ascorbic acid a day, though many of the control children must have been getting under 10 mg a day. Linghorne and his colleagues⁵ have recently found that the frequency of gingivitis was less in groups of men who had 75–80 mg of ascorbic acid a day than among those who had 22 mg.

The League of Nations adopted 30 mg of vitamin C a day as a desirable daily intake. This figure was presumably based on the experiments of Gothlin,⁶ who observed signs attributed to lack of ascorbic acid in individuals after some ten weeks of deprivation, they recovered when allowed 13 to 24 mg per day. Since then Pijoan

and Lozner⁷ have kept one person for fifteen months on a diet which supplied about 20 mg a day, the concentration of ascorbic acid in the leucocyte layer of the blood remained steady, wounds healed, and health remained good, though the concentration in the plasma was near zero. When the intake was 10 mg a day the concentration in the leucocyte layer fell, an indication that the body's stores of ascorbic acid were being used up. Johnson and his colleagues⁸ found that young men can do strenuous work and keep in good health for two months without any ascorbic acid in their food. The Accessory Food Factors Committee of the Medical Research Council showed by experiment (the full results of which have not been published) that individuals could exist on a vitamin-C-free diet for a long time before showing signs of deficiency and, moreover, amounts of vitamin C of the order of 10 mg a day cleared these signs up.

Our outlook on this type of experiment may be changed by one of the results of an experiment conducted by the Accessory Food Factors Committee.⁹ Two persons out of a group who were deprived of vitamin A for over a year were subsequently found to have tuberculosis. They had been examined before the experiment, and no signs of tuberculosis had been observed. The development of tuberculosis or activation of a quiescent focus may or may not have been a coincidence, but it will no longer be possible to start such experiments with the light-hearted assumption that any damage will be slight and reversible. The minor and obvious defects, such as impaired dark adaptation, may be cured by relatively small doses of the vitamin, but the more serious damage remains. Apart from this the results of experiments vary. In other observations by responsible workers on deficiency of vitamin A (for example, those of Booher and colleagues¹⁰ and Steven¹¹) dark adaptation has been impaired far sooner than in the experience of the Accessory Food Factors Committee. And the effects of experimental deficiency are different from those of spontaneous deficiency disease. In clinical scurvy the gums are swollen and bleeding and heal promptly on treatment with ascorbic acid, in experiments, such as that of Crandon,¹² the gums may remain healthy in a person who in other respects is in a very bad way. Vilter and colleagues¹³ have recently drawn attention to the anaemia, curable with ascorbic acid, in cases of clinical scurvy, but anaemia is not observed in experimental deficiency. Again, the Accessory Food Factors Committee found follicular keratosis to be one of the early signs of such deficiency (quoted by Cuthbertson¹⁴), but in many cases of clinical scurvy that occur in England this skin condition is not seen. Both the amounts required and the response to deficiency seem to be influenced by factors we do not yet understand. It is possible that Gothlin's observations, in which one of the first signs, as in scurvy, was swelling and bleeding of the gums, give a better indication of the requirements of the population as a whole.

As the evidence stands at present we may well doubt whether daily intakes of 10 mg of ascorbic acid are sufficient to maintain people in full health, particularly as Linghorne and his colleagues reported numerous complaints from officers that men on a low intake were longer on repair jobs than before, and that a number of them complained that they tired easily. It is essential, therefore, that we should make the fullest use of such sources of vitamin C as we have. Potatoes should not be mashed and should be eaten soon after they are cooked. There is little hope of persuading more than a few people to eat green vegetables raw, even if there were the greens to eat. Mustard and cress are more tempting, and one of the small boxes in which they are sold holds about 2½ oz., which contains about 50 mg of ascorbic acid, the same amount as is contained in one orange. One box a week will supply ascorbic acid at the rate of 7 mg a day. With such other vegetables that can be bought it should be possible to get nearly 20 mg a day.

PENICILLIN DOSAGE

How penicillin can be administered parenterally with the least trouble consistent with efficiency has been a major problem from the earliest days of its therapeutic use. It was for some time assumed that the ideal to be aimed at was the continuous maintenance in the blood of an adequate therapeutic level—a concentration, that is, which would at least inhibit the growth of the micro-organism causing the infection. If this is to be achieved with economy frequent doses are necessary, the longer the interval between them the greater must be not only the individual dose but the total, daily amount given. This policy, carried to its logical conclusion, demands continuous injection, and it is in fact only by the intravenous or intramuscular drip that an adequate blood level can be maintained by an expenditure of only 100,000 units daily. Nevertheless many patients in the early days received this amount of penicillin in the form of three-hourly injections, and although they can have had an adequate blood level only for part of each interval the treatment usually succeeded. We are now seeing the intermittent method in its turn carried to extremes, not of choice but by force of necessity in the circumstances of general practice. We are encouraged to believe that large doses injected only twice a day, or even larger only once a day, will achieve the effects required. Elsewhere in this issue Dr D. P. Whistler gives an account of 7 patients—4 of whom had boils and carbuncles, the others purulent conjunctivitis, a whitlow and a sty—6 of whom responded well to a single daily injection of penicillin in no case exceeding 200,000 units; the single patient who had this dose twice daily is said to have done no better than the rest.

It was suggested in the answer to a question to which this author refers in his opening sentence that a systematic study of the comparative effects of three-hourly and twice-hourly penicillin administration might well be undertaken. We again commend this proposal to anyone in a position to undertake it. Only a controlled clinical trial on a considerable scale can establish the uses and limitations of "massive" penicillin dosage. It may be that too much importance has been attached to blood levels, that diffusion into the infected area, as demonstrated in wounds by M. E. Florey and her colleagues,¹ enables an effect to be exerted locally long after penicillin has disappeared.

the blood. If this is the explanation of the efficacy of large dosage at long intervals it may apply only to certain types of lesion and not to others, for reasons dependent on the rate of formation of the inflammatory exudate. In default of more exact knowledge it is probably advisable to treat more serious cases by three- or four-hourly injection wherever possible. From another point of view it might be said that frequent doses should always be given when this is possible, since they are certainly more economical, our present consumption of penicillin is enormous, and the exportable surplus might be much larger with advantage to the national economy. Possible alternative methods for the future, whereby a continuous effect may be maintained without frequent visits or the services of a nurse, are inhalation, oral administration, and injection in an oil base. All are extravagant methods; the last is the only one by which a single dose will give an effective blood level for twenty-four hours. Although this effect has been obtained in the U.S.A. by Romansky and Rittman² with a highly refined beeswax-peanut oil preparation, we know of no evidence that corresponding preparations available in this country will give so prolonged an effect.

LOUIS PASTEUR

The work of Louis Pasteur is at present being commemorated by an exhibition at the Science Museum, South Kensington. The greater part of the material has been transferred direct from the Palais de la Découverte at Paris, but there is in addition an exhibit by the Wellcome Historical Medical Museum, consisting largely of original manuscripts and apparatus of Pasteur. It is a good thing that the French Government has arranged this exhibition, since Pasteur is one of those men whose greatness in many fields can bear commemoration. The inaugural address to the Exhibition was given by Sir Alexander Fleming, and is printed in full in the opening pages of this week's *Journal*.

Of all the non-medical scientists who have enriched medicine Pasteur is probably the greatest. His outstanding characteristic was the ability with which he cut through the difficulties of a new subject, leaving it thereafter a new science. There was little in his early career to foreshadow such greatness. In an important examination in chemistry—his own subject—his paper was marked "mediocre," yet within a very few years he had differentiated between tartaric and paratartaric (racemic) acids, and shown that the optical differences between dextro- and laevo-rotatory tartaric acid crystals were correlated with minute physical differences in the crystals themselves. This work really laid the foundations of stereo-chemistry.

Perhaps the most lengthy of all Pasteur's investigations were those which he devoted to the subject of fermentation. He began these just after he went to Lille in 1854 as Dean of the Faculty of Science, and they were continued, with some intervals until 1876 when his great work *Etudes sur la Fermentation* was published. Quite early Pasteur showed that if a solution of pure sugar containing ammonium phosphate and some chalk is allowed to stand, a gas is evolved, and lactic "yeast" settles at the bottom of the vessel. He thought that the ferment probably came from the air, since the reaction did not take place with heated air. He stoutly maintained that yeast is a living organism, and in doing so incurred the lasting hostility of Liebig. These lactic acid studies formed the foundation of all Pasteur's fermentation studies, and indeed of the science of bacteriology. They led to his important work on negar and the souring of wine, and finally on diseases of beer. It has been said that Pasteur was a practical worker

rather than a theoretical scientist, and in all these subjects Pasteur's work led to marked improvements in the processes of manufacture or storage of the respective beverages.

These researches also gave Pasteur a method of filtering the air which was admitted to potentially putrescible liquids. They thus enabled him to enter the strictly bacteriological field in an attempt to disprove the theory of spontaneous generation. Almost at the start he carried out experiments which attained their end, and his *Memoire sur les Corpuscules Organiques qui Existent dans l'Atmosphere* (1862) is a classic of science. Pasteur proved that air contained germs, but that it was possible to supply heated air to a boiled infusion without the latter being affected. However, if unheated air is subsequently introduced the infusion is infected. He further demonstrated that atmospheric air can be admitted to a putrescible medium without infection taking place, provided that the air enters through a long neck which is so bent as to trap the germs. These important results were extended almost at once by Tyndall, and Pasteur and Tyndall were jointly responsible for the final overthrow of the theory of spontaneous generation.

Despite the fact that Pasteur is the father of modern bacteriology, he and his followers discovered few new organisms. Pasteur's mind began working in the direction of prevention. His earliest practical application of his views was in connexion with a disease of silkworms (*pebrine*), and very soon he was absorbed in his experiments on the prevention of anthrax in animals. His work on chicken cholera led to his methods of attenuating organisms for injection (1880), and on this foundation rests the modern science of immunology. His final and greatest effort in this field was his research on rabies, a disease which appealed greatly to the popular imagination.

During his lifetime the Royal Society twice honoured Pasteur. In 1856 he was awarded the Rumford Medal, and at a later date the Society gave him its highest honour—the Copley Medal. His own country has honoured him by the foundation, among other institutions, of the Institut Pasteur and its many branches. As Bulloch said, "There is no department of bacteriology that he did not enrich by his genius."

OCCUPIED HOLLAND

Holland is one of the most thickly populated countries in the world, and about one-fifth of its area lies below sea-level. Most of its people live in the three small industrialized provinces of Utrecht, North Holland, and South Holland. Before the war the health services were of an excellence appropriate to the high standard of living enjoyed by the Dutch—a way of life that was nevertheless precarious, depending as it did on a complex drainage system and trade with a great overseas empire.

The withdrawal in September, 1944, of the remnants of the First Airborne Division across the Lower Rhine, while for us merely postponing the possibility of victory over the Germans until the following year, was a major disaster for the whole Dutch nation. Starvation fell upon the land, afflicting especially the inhabitants of the cities and larger towns, and was accompanied by those diseases that flourish in an underfed, cold, overcrowded, and ill-housed population. The Chief Medical Officer of Public Health in the Netherlands, Dr. C. Banning, elsewhere in this issue (p. 539) explains what this meant in terms of death and disease. The rapid spread of tuberculosis, acute poliomyelitis, and typhoid fever was something which could have been predicted. Quite unpredictable was the rapid increase in the number of cases of diphtheria—50 times the 1939 figure—and also the relatively high number of adults affected.

² *New Engl. J. Med.* 1946, 233, 577.

Dr Henriette A Lohr (p 540) describes the effects of starvation and malnutrition. Her findings correspond closely with those of other observers in this field.

Conditions were at their worst during February and March of 1945, and were aggravated by an unusually cold spell of weather which froze many of the canals. The official ration was reduced to 340 calories a day, but many were too weak to stir out of doors to collect even this. In the three industrial provinces, the so-called B2 area or western district, 15,000 people died of hunger, and 80,000 cases of hunger oedema were known. First the Swedish Red Cross, and later airborne supplies from Britain, provided a certain amount of food, but lack of internal transport rendered distribution difficult. In contrast to this tale of disaster Dr J G G Borst (*Supplement*, p 57), the professor of medicine at Amsterdam University, shows how a well-organized and united medical profession was able to thwart the dictates of their German oppressors. In the main it was by means of passive resistance, since active resistance by the medical profession as a whole can result only in harm to their patients. Dr Borst writes that "the medical profession was also the only section of the population which unflinchingly and successfully resisted the encroachments of the Compulsory Labour Service." For many this meant the added discomforts of going into hiding—"under water," as they called it—and, for others, terms of imprisonment. Dutch doctors also played an active part in the resistance movement. Many wounded soldiers and airmen stranded in occupied Holland owe their lives and subsequent freedom to the skill and courage of the doctors and nurses. Because of their professional duties they were allowed greater freedom of movement than most civilians, and they made excellent liaison officers between various sections of the resistance movement.

Like us, the Dutch are suffering from a shortage of hospital accommodation and, to an even greater extent, from lack of trained nursing staff. However, they are hard-working people, and they are rapidly rebuilding their homes, their standard of living is now well above ours, and the flooded fields are again under the plough. Wooden huts have been ordered from Sweden to provide sanatoria for the many cases of tuberculosis resulting from the war. Those who were privileged to be with the Dutch behind the German lines during the winter of 1944-5 felt nothing but admiration for them. Doctors and nurses short of food and medical supplies spared themselves no pains for the sake of their patients. In spite of all difficulties they retained their professional integrity.

CUTANEOUS DIPHThERIA AND THE HEART

Absorption of diphtheria toxin from the usual site of infection—namely, the tonsillo-pharyngeal area—gives rise to myocarditis in a proportion of cases which may vary from 10 to 25%. Thus in 1922 Schwensen¹ recorded a rate of 17% in a series of 568 cases, 118 were classified as "severe," and there were 8 deaths. At the Herman Keeser Hospital, according to Top,² 21% of 1,828 cases were affected. Such an incidence includes both the early manifestations such as heart block, which is often fatal, and the late disturbances of rhythm from which death is less usual. Burkhardt, Eggleston, and Smith,³ who analysed the results of clinical and electrocardiographic studies in 140 patients with diphtheria, divided their cases of myocarditis into two groups. A first group of 23 patients showed mainly alterations in the S-T wave and lowered amplitude of the T wave. These changes occurred on an average 15 days from the

onset of the disease with a range of 5 to 39 days. The second group of 17 patients showed conduction defects which were noted earlier—on an average 8 days after onset with a range of 5 to 13 days. An interesting finding was that the latter changes took place in a much younger group of patients than the former. Most of the patients who developed signs of myocarditis also showed signs of some form of nervous lesion. Alsterd⁴ recorded somewhat similar changes and in a later paper⁵ suggested that a negative or isoelectric T-wave might in recovered cases persist for many years.

When diphtheria toxin is absorbed from the skin the picture presented is not so clear. Although most cases are diagnosed late and many have peripheral nerve lesions, a much smaller proportion develop myocarditis. Kay and Livingood⁶ have recently analysed a series of 140 cases of cutaneous diphtheria in the India-Burma theatre of war. The bacteriological diagnosis was not entirely satisfactory under field conditions, but judged by the extent of the local ulceration there were 50 mild, 72 moderate, and 18 severe cases, with only one death. Myocarditis developed in 4 of the severe, in 3 of the moderate, and in none of the mild cases. Electrocardiographic studies were made repeatedly, and the most frequent abnormality was depression or inversion of the T wave—a change which appeared usually between the fourth and seventh weeks, 4 of these patients had peripheral nerve damage. Such findings run parallel to those of Cameron and Muir,⁷ who in 66 cases found paralysis in 12 but made little comment on cardiovascular changes beyond noting that the only fatality was due to circulatory failure. Myocarditis would thus seem less frequent, less severe, and rather later in appearance in the course of cutaneous diphtheria. That severe circulatory failure occurs is undoubted, indeed it was the sudden death of one of their early patients which aroused Kay and Livingood's interest in the subject.

The inclusion of many mild infections in the records of cutaneous diphtheria might in part explain this difference. Once the condition is kept in mind the diagnosis may become common in the Tropics, for skin sores abound and bacteriological examination often yields positive results even in quite atypical lesions. Clarkson⁸ found diphtheria bacilli in 20 out of 30 infected wounds, but although 2 cases developed peripheral neuritis he did not seem to regard the infection with undue alarm. Chronic wounds particularly showed a high incidence of *C. diphtheriae*. It is a pity that such cases arise in appreciable numbers only under conditions which preclude examination of the patient's immune status, even the results of Schick-testing would be valuable in their assessment. But this cannot be the explanation, for in the series analysed by Kay and Livingood 43.5% of the cases developed a nerve lesion. The other reason may lie in the fact that diphtheria is carried more rapidly and easily to the medullary centres from faucial lesions and that in cutaneous diphtheria the centres are, therefore, to some extent spared, with a consequent reduction in late circulatory defects. Despite extensive work on the cardiac complications of diphtheria there is still need for further study to elucidate the relative importance of peripheral and central damage in its pathogenesis.

We announce with regret the death of Dr C. Lo Leipoldt, formerly Editor of the *South African Medical Journal* and Medical Secretary of the Medical Association of South Africa.

OCCUPIED HOLLAND

I THE PUBLIC HEALTH

BY

C BANNING, MD

Chief Medical Officer of Public Health in the Netherlands

Before the war Holland ranked among the highest of nations regarding health. The death rate of babies was extraordinarily low. During the war the mortality rate increased regularly without, however, the summer top feared so much in former times. Immediately after the liberation, in the summer of 1945 in spite of the good food supply the death rate of babies was so high that we could again speak of a 'summer top'. Many babies died within a few days with toxic appearances for which we could find no definite cause. Necropsy revealed no obvious reasons for the deaths. Per 1,000 born live there died in the whole kingdom

	Under 1 Week	1 Week to 1 Month	1 Month to 1 Year	Total
1939	15.5	4.3	13.9	33.7
1940	16.0	5.3	17.9	39.1
1941	16.5	6.2	20.9	43.4
1942	14.5	4.4	18.5	39.8
1943	14.2	6.3	19.8	40.3
1944 (1st half year)	15.5	7.4	20.7	43.5

As regards infectious diseases Holland could be proud of its abnormally small number of cases. During the war diphtheria spread in a startling manner, and it was observed that the higher age groups were gradually being affected in large numbers. The epidemic started in 1942, in the southern provinces and in the course of the next year or two spread over the whole country. In spite of the high figures recorded the number of cases is believed to have been still higher for owing to poor communications many doctors were unable to report all the cases to the Inspector of Public Health.

Besides the steep rise in diphtheria there was an abnormal increase in the number of cases of typhoid fever. Already in 1942 and 1943 cases were nearly five times as numerous as in pre-war years but in the first six months of 1945 the rise was still more startling. How could it be otherwise? Families were herded together under extremely bad hygienic conditions. Thousands of houses and many water pipes had been destroyed, medicines, disinfectants, and coal were scarce and there was a total lack of soap. Fortunately the number of cases of typhoid is now declining. Scarlet fever also showed a rise, but not to the same degree as diphtheria and typhoid.

Reported Cases of Illness				Reported Deaths			
	Diph- theria	Scarlet Fever	Typhoid Fever	Acute Polio- myelitis	Diph- theria	Scarlet Fever	Typhoid Fever
1939	1,273	10,257	172	403	75	24	25
1940	1,770	8,841	108	111	103	34	21
1941	5,457	7,197	161	445	213	35	21
1942	10,007	12,694	521	196	873	35	27
1943	16,000	25,466	531	1,931	2,515	23	50
1944	60,226	22,470	472	1,180	7	76	222

* Provisional figures

Tuberculosis

Tuberculosis causes much concern. All our strength will have to be exerted to combat this illness. The following table shows the rise of the total death rate of tuberculosis as well as the death rate per 10,000 inhabitants and the increase per cent over 1939.

	Total Deaths from Tb	Deaths per 10,000 Inhabitants from Tb	Increase over 1939 (%)
1939	3,600	4.10	—
1940	4,051	4.37	6.6
1941	5,005	5.92	44.4
1942	7,445	8.13	50.0
1943	6,557	6.99	70.5
1944 (1st half year)	7,289	8.75*	102.0*

* Calculated on death rate per annum.

The fight against tuberculosis in Holland is carried on in Tuberculosis Consultation Bureaux. Holland is divided into districts each having a consultation bureau with branch consultation bureaux in the smaller places and it is possible for every citizen to visit them. Admission to the bureaux is free for everybody from the poorest to the richest. The work of the consultation bureaux is to detect contact cases. The rise in tuberculosis can be noted not only from the mortality rate but from the increased number of cases which visit the consultation bureaux. In 1939 the new registrants were 60,377, in 1942 122,795, in 1943 157,844. In 1939 the consultation bureaux reported 13,560 cases of tuberculosis in 1942 24,622 and in 1943 27,981.

A recent investigation of the bureaux showed that 50,000 cases of tuberculosis are known in the Netherlands. Thousands have to wait for months for admission to a sanatorium. All the sanatoria are filled to capacity and it will take years to reach the favourable pre-war standard. Sanatorium and hospital facilities are being increased by providing wooden barracks, 300 of these having been ordered in Sweden. Every barrack will house 18 patients. Our greatest trouble is not lack of equipment but lack of medical and nursing personnel.

A Period of Malnutrition and Starvation

Malnutrition did not appear over the whole of Holland but only in the so-called B2 area or western district (the provinces of Utrecht, North Holland and South Holland). In these provinces live half the population of the Netherlands—namely, 4 to 5 millions. The big cities—Utrecht, Amsterdam, Haarlem, Leiden, The Hague and Rotterdam—are situated in the B2 area. When the Allied Forces marched into Nijmegen and Arnhem (September 1944) and our Government in London ordered a universal railway strike the whole railway personnel obeyed. The Germans closed our non-agricultural provinces from the agricultural northern and eastern provinces as a reprisal. Seyss-Inquart laid an embargo on all the provisions which were transported from the north and east to the west, in order to maintain our already small rations. By this closing and also because the Germans took away every means of transport, the western district was doomed to hunger.

The reserve of provisions in the western district was in such a state that the disaster already foreseen became a reality. The winter of 1944-5 was the winter of the notorious "hunger journeys." Officially no provisions were allowed to be transported, but it was often possible for people to break through the German line towards the north and the east. In that cold winter thousands of girls and women on bicycles without tyres or with a hand-cart, etc., badly dressed with poor footwear, and starving went in search of food. Journeys of 100 to 200 miles (160 to 320 km) were no exception. They came home laden with 30 to 50 kg of potatoes and some wheat, and could live for a few more weeks on that. Men between 16 and 50 years of age did not dare to show themselves in the street as they were constantly being rounded up and deported to Germany; consequently our women and girls had to carry out this almost superhuman task.

During the winter the population of this B2 area lived without light gas heat, laundries, soap or enough clothing, blankets, and food. Tulip bulbs and sugar-beet (officially distributed) plus some bread of very poor quality, were all we had to live on. After October, 1944, butter and animal fats were no longer distributed. As for other fats from September 1944 to the end of March 1945—7 months—1.3 litres of oil was distributed per head which means less than 0.2 litre per month. Officially there was also 100 g of cheese per month but often meat coupons were of no value because no meat was available. The bread ration gradually decreased. In the course of the war it had come down from 2,200 to 1,800 g a week then to 1,400 g and later to 1,000 g. In November 1944 it was 800 g, and in April, 1945, 400 g a week. Potatoes were rationed at 1 kg a week, but were hard to get.

As for the number of calories that were officially available per person I submit the following figures:

In the last week of Oct., 1944	about 1,300 cal. per day
Nov., 1944	900
Dec., 1944	550
Jan., 1945	460
Feb., 1945	340

Owing to the close co-operation of the Catholic and Protestant Churches the so-called "latent" supplies present in the B2 area could be mobilized, and because of this activity many thousands of Dutchmen were able to hold on a little longer until, in the course of the first quarter of 1945, the Swedish Red Cross brought some relief. The number of calories could then be increased to 525, and it was possible to distribute a food parcel of 700 calories a day for some weeks. But the last weeks of April, 1945 brought a severe cut—viz., to 400 calories a day. During the week before the liberation there was nothing left in the western district. Just for a few days a distribution of 230 calories a day, and then—no more. And in the very depth of this misery came the "finest dropping of the war," and Allied bombers threw out manna from Heaven. The German ration of 230 calories a day during the last days of April, 1945, was changed into the weekly "Allied" ration of

800 g bread	125 g meat	$\frac{1}{2}$ tin bacon
900 g biscuits	100 g cheese	2 bars of chocolate
200 g fat	200 g beans and peas	1 kg potatoes
100 g butter	200 g sugar	1 litre milk

Consequences of the "Hunger Rationing"

The first cases of death as a consequence of hunger were officially registered in the beginning of January, 1945. The death rate from hunger increased rapidly each week. Altogether at least 15 000 people died of hunger in B2 area, while about 80 000 cases of hunger oedema were known. First I will give a survey of the general death rate in the four big cities of the western district in the first half of 1939, 1944, and 1945.

Community	General Death Rate 1st Half year			Ratio (1939 = 100)			Death Rate per 1 000 Inhabitants		
	1939	1944	1945	1939	1944	1945	1939	1944	1945
Amsterdam	3 655	4 399	9 735	100	120.2	266.3	4.60	5.69	12.61
Rotterdam	2 616	3 260	7 827	100	124.6	299.2	4.25	5.39	12.94
The Hague	2 419	2 940	6 458	100	121.5	267.0	4.86	6.50	14.38
Utrecht	776	1 112	2 065	100	143.2	266.1	4.67	6.54	12.15

The death rate was greatest in February and March, when food rations were smallest. In the smaller towns the death rate increased in almost the same ratio as in the big cities, while the rate in the country districts, although increasing, was not so serious as in the towns. It is remarkable that in the big cities the death rate of men was much higher than the death rate of women. It is not clear to what causes the higher death rate among men was due. Heavier work was not a likely cause, for many factories and offices were either forced to a standstill or had to carry on with a greatly decreased working time. The women did wonders in the way of physical effort—it was they who went out for food under the most unfavourable conditions. Moreover the high male death rate occurred in all age groups, including infants and the groups over 50 years. As hundreds of thousands of men had already been deported to Germany and others had "gone underground"—i.e., they hid somewhere in the country—the death rate for men might have been still more unfavourable. It is now known that 75% of those who died from malnutrition were men.

Death Rate from Malnutrition in The Hague in 1945

Age Group	Total Death Rate			% of Dead from Malnutrition		
	1st Quarter 1945	2nd Quarter 1945	Half year 1945	1st Quarter 1945	2nd Quarter 1945	Half year 1945
Under 1 year	28	24	52	2.12	3.09	2.48
1-4 years	14	11	25	1.06	1.41	1.19
5-9	5	0	5	0.38	—	0.24
10-14	0	2	2	—	0.26	0.10
15-19	3	1	4	0.23	0.13	0.19
20-24	10	4	14	0.76	0.51	0.67
25-29	12	7	19	0.91	0.90	0.90
30-34	13	9	22	0.98	1.16	1.05
35-39	16	10	26	1.21	1.28	1.24
40-44	43	20	63	3.26	2.57	3.00
45-49	62	29	91	4.70	3.74	4.35
50-54	90	36	126	6.83	4.63	6.01
55-59	153	62	215	11.60	8.00	10.26
60-64	154	93	247	11.67	12.00	11.80
65-69	586	373	961	44.43	48.32	45.87
Over 80 years	130	93	223	9.86	12.00	10.65
Total	1 319	776	2 095	100%	100%	100%

What strikes one when examining the death rate from malnutrition is the fact that persons in the older age groups were

those mostly affected. This is exemplified in the figures for The Hague given in the preceding table. Consequently in The Hague as many as 84% of the deaths due to malnutrition were of persons over 50 years while 56% were of those over 65. In the age group 5-35 years there were very few deaths—in The Hague only 3.14% of the total. The growing up period of 5-19 years came out exceedingly well, whereas the percentage for the infants was fairly high. I dare not say to what degree the combination of hunger plus cold played its part in this trouble. Though I give only the figures for The Hague, those for the other big cities in the western district (Rotterdam, Amsterdam, Haarlem, Leiden, Utrecht) show exactly the same picture. The western district paid heavily for this war, suffering as it did from so severe a famine.

Relief Measures

And now for the question how we combated the hunger. On May 3, 1945 some days before the German Headquarters capitulated consequently when the war was still going on in B2 area, four Allied officers entered that area. It was the "Advisory Committee" for the "Special Feeding Teams" who were ready in the southern part of our country to help B2 in its great need. The leader of this "Advisory Committee" was Sir Jack Drummond (England), the others were Dr. Leach (USA), Dr. Beattie (England), and Dr. Loutit (England) together with myself. The 50 special feeding teams (each of them with a doctor as its leader) were distributed over the most threatened places in B2. Their activities started in the hospitals, later on they shifted to the polyclinics. The teams brought specially prepared food, together with laboratories and instruments. At the same time large quantities of food were dropped on the aerodromes and loaded ships came up "Waterweg" to Rotterdam, while from the east via the province of Gelderland, thousands and thousands of tons were brought by trucks. The result of all this was that by May 15 there was a considerable decrease in the number of deaths from malnutrition—a decrease which continued till the beginning of August, when it disappeared altogether.

II CLINICAL IMPRESSIONS*

BY

DR. HENRIETTE A. LOHR

Amsterdam

Whereas in Paris hunger osteopathy was seen as early as 1941 the first case of osteomalacia caused by food deficiency in Holland was described in March, 1943. Afterwards there were many cases of hunger osteopathy.

The chief symptoms in hunger osteopathy are pain and stiffness of the back, the lower limbs, the feet, and now and then also in the arms and ribs. The patients move about in a curious stiff way, and when rising out of a chair have to heave themselves up by their hands. Coughing and sneezing may be painful. In some cases, as the complaint was thought to be of rheumatic origin, gold therapy had been tried, but in vain. On x-ray investigation one finds translucent notches or bands of decreased opacity, so called looser zones where the bone has been replaced by osteoid. They are located chiefly in regions of stress and strain. In some cases there are deformities with callus formation. Hunger osteopathy is regarded by certain authors as "the result of a combined deficiency of multiple food factors, of which animal protein might be one and of which vitamin D is probably the most important." Untreated hunger osteopathy develops progressively into typical osteomalacia. Twenty-two of our cases occurred in women. We are inclined to ascribe this peculiar sex distribution to a difference in food habits between men and women, rather than to hormonal distinction between the sexes. Generalized osteoporosis is often present, but may be slight in early cases. Our cases improved with rest in bed, a full diet especially rich in animal protein and calcium (milk) with extra vitamin D by mouth or by injection. The patients lost their pains within two weeks. X-ray examination demonstrated objective improvement within two months. It is our impression that vitamin

* Abridged from an address to the London Association of Medical Women's Federation, Sept. 24, 1946.

was the most important therapeutic agent. It made no difference whether the vitamin was given by mouth or by injection."

From 1944 children were seen with Barlow's disease, which had become unknown in Holland, and rickets was increasing rapidly. Pellagra was observed in psychiatric patients from 1941, and afterwards cases occurred in mental hospitals, though they were fewer than had been anticipated. There were, however, many cases of perniosis, which probably had some connexion with nicotinic acid deficiency, and mouth and tongue sores, which undoubtedly had. The same can be said of beriberi: we did not see many definite cases, but there was an unusual number of patients with polyneuritis and there still is. From 1942 we all had polyuria especially at night, quite frequently amounting to more than 3 litres a day. It must be considered as a latent oedema.

Food poisoning by mushrooms and by beech nuts was seen from 1942. Up to 1943 there had been 223 cases of the latter. Beech nut poisoning is characterized by intestinal troubles, severe headache, difficulty in breathing, a cloudy effect on the brain and in some cases a rabies-like condition. It can be avoided by removing the germ of the nuts. The illness passes in a few days and is never dangerous. Botulism brought about a state resembling myasthenia gravis.

Partly as a result of the coarseness of the food and partly owing to psychic strain, cases of ulcer of the stomach and of the duodenum increased. Stolte and Beaumont state that at the Onze Lieve Vrouwe Gasthuis at Amsterdam during the 44 months from January, 1936, to September, 1939, there were 392 ulcer cases in the wards, whereas during the 46 months from September, 1939, to July, 1943, there were 633. The number of ulcers of the lesser curvature was relatively higher than before the war and the perforations had increased considerably.

Treatment of diabetes mellitus became very difficult on account of the lack of insulin and of suitable food. All diabetics except the very severe cases had to do without insulin and had to be reduced to hunger diets. During the 'hunger winter' these were symptom free though sugar-beet was their principal food. Afterwards they suffered severe relapses. Lack of fuel during the very cold winters of 1941 to 1944 was the cause of a much higher incidence of rheumatic diseases and perhaps also of nephritis. The latter, however, was apparently contagious like trench nephritis during the war of 1914-18. It was characterized by severe uraemia and oedema with a blood pressure that was only moderately high. Blood pressure in general had a tendency to be lower than usual, probably because of undernourishment.

Poliomyelitis and Diphtheria

During 1943 there was a bad epidemic of poliomyelitis and its contagiousness was clearly demonstrated in a home for children. Most of our bacteriologists now adhere to the theory of faecal infection. Lack of soap may have influenced this epidemic. We always have had some cases, mostly during the summer months in Amsterdam they amounted to 8 or 9 a year. During 1943 in Amsterdam alone 655 cases were notified and there probably were many more. The abortive form with intestinal trouble, headache and moderate temperature is not easily recognized and cannot be detected from the specific reactions in the spinal fluid as during an epidemic these reactions are positive in many who have not been manifestly ill. These persons must all have undergone infection and gained immunity as a consequence. In the course of one year the population may be said to be 'durehseucht' as the Germans call it. To be sure in the next year there were only 51 new cases.

Already in 1941 the figures for diphtheria were showing a tendency to rise. In Amsterdam new cases were shown to belong to the *intermedius* and not to the local *mitis* strain. The next year brought a very bad epidemic and this time it was caused by the *gravis* strain which had been imported from Germany. From a mean figure of 100 cases a year in Amsterdam we had nearly 8,000 cases in 1944 among which were many severe infections with early death from toxæmia or paralysis even after many months. The infection moreover was made worse by the lack of serum and could not be controlled until after our liberation when we were able to

obtain the potent new British sera. During this epidemic many adults fell ill, even those who had had diphtheria before, as the former *mitis* infection gave no protection against this new strain. This epidemic therefore proved fatal to many adult people as well as children.

Hunger Oedema

The official report of the percentage of people with hunger oedema during the spring of 1945 has not yet been published. Most of the population were showing some slight degree of oedema, and all of us had nocturia. In many people the oedema did not become manifest until the summer, when we had salt again. The oedema still has a tendency to return, perhaps because our food is poor in protein. Though there is a predilection for the lower parts of the body, other parts may become involved through various causes—for instance, local infection or mechanical irritation. A very frequent location was the face. In oedema formation the protein content of the blood plasma is not the only factor, for in some cases of oedema the blood protein was not lowered at all. Prof. Formyne is of the opinion that hunger oedema has some features in common with nephritic oedema as regards distribution, the possible normality of blood proteins, and the lack of a rise in venous pressure.

With regard to the last feature however, Stolte has pointed out that the tissue pressure is very much lowered as a consequence of the loss of fat and part of the muscle tissue. There is a curious contrast between the dry leathery skin in some parts which is loose and can be lifted up in big folds, and the solid oedema in other parts. Venous pressure cannot be high with such a low tissue pressure. In another respect there is a difference between the nephritic oedema and hunger oedema as the latter is low in protein. Renal function was normal and there were no indications of cardiac insufficiency. Most people had a very pronounced bradycardia and lowered blood pressure. Damage to the capillary wall must be an important factor, as the Rumpel-Leede phenomenon was always present. Low tissue pressure is another factor, and lowering of blood albumin plays a part in some cases.

Dr. Adelsberger, from her experiences in German camps, made a distinction between two types of starvation—a dry form and one with oedema. We had the same experience in Holland, inasmuch as between February and May, 1945, people collapsed in the streets and died from starvation, with very low body temperatures, showing little or no oedema and sometimes not seeming so very thin either, the latent oedema having taken the place of the intertissue fat. During this cold winter body temperatures of 27-29°C were not uncommon in these people and most of them died. It proved very difficult to raise these low temperatures. After our liberation the number of patients with manifest oedema increased considerably. Even with a very poor diet and rest they would sometimes lose their oedema in a short time showing a diuresis of 3-5 litres a day. All of these patients had anaemia, sometimes in a macrocytic form which was not cured either by iron or by liver. It was not the deficiency anaemia of Lucy Wills, but rather an aplastic form, the bone marrow showing very little activity. It responded to proper feeding very slowly, and then often changed into a hypochromic anaemia, which reacted to iron.

Psychic factors were an extreme lassitude and apathy, with considerable irritability. Anxiety states and psychosis were sometimes seen. Many elderly people took to their beds and died because they could not be bothered with the trouble of standing in queues to get a pint of thin soup. Others were frozen to death from lack of fuel. The Bureau of Churches has done much good work in seeking out and feeding these people.

Polyneuritis was and is still a common disease. In some rare instances there was a neuritis of the optic nerve with central blindness, weakness of the muscles, considerable muscle irritability and a tendency to cramps, which persists in some. The blood calcium was lowered in many instances. Chvostek's sign and Trousseau's phenomenon were only occasionally present.

Many people had intestinal troubles, which were aggravated by the diet of sugar-beet and tulips. For some time we had half a loaf of bread and 4 kg of potatoes for the whole

and nothing more, these rations amounting to 300 calories a day. Though people went far afield to get food, they often returned with little or nothing, and were weakened by days of walking or cycling.

People who collapsed, standing in queues or going about the little work that was yet done, did not show orthostatic hypotension, but a low blood sugar. They swayed some time before actually falling down, sweated and seemed completely dazed. In extreme cases of starvation hunger disappeared and food was refused because of difficulties in swallowing. In elderly persons death from cold was caused by lack of fuel, but at the same time there may have been a deficiency of the thyroid gland as a result of starvation as at necropsy the gland was found to be small and leathery. Basal metabolism was lowered in most people from 20 to 30%. Strange as it may seem during a period of hunger, in cases of hypothermia some advocated the use of thyroid.

A curious feature was that some girls and young women got fat on a diet totally insufficient. This condition is probably a mixture of myxoedema and hunger oedema, but the oedema is not demonstrated very easily. It is difficult to cure this condition with our present food supply. Even now there is a serious lack of protein and a relative abundance of carbohydrates. These patients are not benefited very much by thyroid extract. They complain of weakness and severe headaches, which sometimes are made worse by thyroid therapy. Treatment of starvation with or without oedema has consisted in rest in bed and a diet of skimmed milk with glucose and vitamins. Very slowly the food intake has been raised. Kaolin, lactic acid, charcoal, and opium proved of value in the treatment of intestinal trouble. Intravenous therapy of casein preparations, amino-acids, and blood or plasma transfusions did not prove of much value.

We have learned some things during this hunger period. Even those who didn't get oedema have experienced a curious change in their outlook and behaviour, which varied from complacency and apathy to irritability. Formerly we may have scoffed at the poor for not being able to grasp the many opportunities which life offers to better their conditions. We never realized the fundamental significance of food. People who have been starved many times, like the Indians, are apt to have an outlook on life and a standard of behaviour different from those of more fortunate ones. There is to-day nothing perhaps of more importance than the effort to obtain food control for the whole world and nothing more necessary than to improve upon it until it is possible to provide adequate food for all countries and for every man and woman and child of the community. Not until this is achieved will it be possible to assess the intellectual and moral qualities of the various races or to expect their willing and active co-operation towards pacification and unification of the world.

THE PASTEUR EXHIBITION

The United Nations Educational, Scientific, and Cultural Organization (Unesco) organized last year, as part of its International Month, an exhibition commemorating Pasteur, which was shown at the Palais de la Découverte in Paris. This has now through the co-operation of the Cultural Relations Department of the French Foreign Office and our Ministry of Works, been brought to the Science Museum, South Kensington, where it will be on view free until May 26. It was opened on April 9 by M. René Varin, the Cultural Counsellor to the French Embassy in London, who said that perhaps Pasteur's most striking quality was his patience, which exemplified the aphorism that genius is a capacity for taking infinite pains. Throughout his life he had never set himself a plan of research but had let problems come to him. The work which had first made him famous has led to his revolutionary discoveries on the nature of fermentation by which he had discovered the traditional notion of spontaneous generation. From that he had passed to diseases of silkworms, anthrax, fowl cholera, swine fever, and rabies. His love of science and humanity was entirely altruistic. He was completely indifferent to the standing of the persons he helped, and although he had had many

opportunities of self enrichment he had neglected them. He was an intensely religious man and spent the night awake and at prayer before he first used his antirabic serum on a human patient.

France was naturally proud of Pasteur, the more so because his qualities of tenacity and patience were relatively rare among Frenchmen. These very qualities had perhaps served to link him more closely with his English hosts, for whom he had performed some of his most notable work. Visitors would see an admirably penned letter in French from Lord Lister to Pasteur, and another in which Pasteur acknowledged the inspiration he had received from the works of Lister and Jenner. The intimate connexion of these three great men, in their will to help humanity, was a strong tie between their two countries.

Sir Henry Dale regretted that His Excellency the French Ambassador M. Massigli, could not be present but thanked him, M. Varin and his colleagues, and M. André Léveillé, Director of the Palais de la Découverte, who was directing the temporary installation of the exhibition in London. Dr H. Shaw, the director of the Science Museum, had co-operated in arranging for this display, to the great gain in instruction and interest of all who visited it. An important addition had been made by the loan of a collection from the Wellcome Historical Medical Museum, and by the specimens lent by the Dewar Laboratory at Edinburgh and Messrs. Whitbread. The exhibition gave visitors the opportunity and privilege of recalling vividly with intimacy and detail the life and scientific achievement of one of the greatest of all the distinguished sons of France and one of the outstanding figures in the science of all the world in all the four centuries since modern science had begun. No adequate estimate could be made of the value in human health, happiness and prosperity of all Pasteur's discoveries. His marvellously consistent career, which the exhibition served to teach and reinforce, pointed however, one lesson. Pasteur did not set out on his life's work with even a thought that it would lead to discoveries revealing the nature of fermentation, putrefaction or eventually of infectious diseases as due to specific living micro-organisms. He did not even start as a biologist, but as a mineralogist and crystallographer. His first great discovery, which at the early age of 34 had won for him the Rumford Medal of the Royal Society, had been of the crystallographic and optical asymmetry of the two kinds of tartaric acid. From that discovery he had followed the natural lead of his genius to recognize the connexion between such asymmetry and the chemical activities associated with life. Thus in logical and unbroken sequences he had come to discover living organisms as the causes of fermentation, putrefaction and infectious diseases to expose the fallacies in all the appearances which had led men to believe in spontaneous generation and to lay the scientific foundations of all our knowledge of specific immunity. These discoveries had led to revolutionary changes in the conditions of civilized existence and represented an almost incredible sum of achievement for one man's life, but they represented the achievement of one who throughout his life remained a single-minded seeker for truth for its own beauty and interest who had humbly accepted Nature's answer to his inspiring questions and faithfully followed the clue wherever it led.

Sir Henry concluded by saying he hoped the exhibition would strengthen still further the ties of intellectual and cultural sympathy and of scientific comradeship between France and Britain, and that as in Pasteur's day, so now the work of scientists would help both peoples to rise above the losses, injury, and deprivations which a greater and even more cruel war had left in its train.

Dr H. Shaw, Director of the Science Museum, moved a vote of thanks to the French authorities for placing the exhibit at the disposal of the Science Museum and for the strenuous work they had done to make it ready, and to the other contributors to its success.

The exhibition includes several portraits of Pasteur, masters, disciples, friends and colleagues, enlarged maps of Strasbourg, Lille and other towns and districts he lived in, pictures of the Ecole Normale where he investigated molecular dissymmetry of Salins and Monteviers where he worked on spontaneous generation and other places famous by association with him, and of members of his

Vitamin Therapy - its uses and limitations

SUSCEPTIBILITY TO INFECTION

is, for a multitude of reasons, high in the Spring months. This year in particular, lack of sunshine, increased exposure to cold, fatigue and the difficulty in obtaining fresh garden and farm produce have combined to produce the conditions which are often the predisposing factors.

Dietary protection can best be assured by the regular consumption of the essential nutrients in the quantities in which each is known to be deficient in the average diet.

COMPLEVITE has been designed especially to meet this requirement.

COMPLEVITE

A single supplement
for multiple deficiencies

The recommended adult daily dose provides —

vitamin A 4000 i.u.	vitamin C 20 mg	iodine	} not less than 10 p.p.m. each
vitamin D 300 i.u.	calcium 160 mg	manganese	
vitamin B ₁ 6.6 mg	iron 68 mg	copper	

Shortage of space precludes list of references but full documentation may be obtained on application to Clinical Research Dept. A12

Vitamin Therapy - its uses and limitations

ANXIETY: FATIGUE: INSOMNIA: CONSTIPATION

may be signs of exhaustion or neurasthenia. But their combination in one patient may also indicate that diet has been at fault and that the patient needs extra vitamin B. If the extra calorific intake necessitated by the prolonged cold weather were not balanced by the vitamin B group which is concerned in carbohydrate metabolism, a partial deficiency might easily have arisen. To restore the patient to normal, the most effective remedy is a combination of the factors concerned, namely

BEFORTISS B-complex capsules

Each capsule contains

Aneurin hydrochloride 1 mg	Riboflavin 1 mg
Nicotinamide 15 mg	Pyridoxin 0.5 mg

WESTMINSTER LABORATORIES LTD
Chiswick Road, London NW1

*Rx Tri-
Antiseptic*

SIX times as strong as carbolic acid (R.W. coefficient), non-poisonous, non-irritant and extremely pleasant to use. Tri-antiseptic contains three compatible substituted cresols carefully selected to provide a wide range of bactericidal activity.

Tri-antiseptic contains no soap, and in the hardest tap water gives a fine colloidal suspension. Due to its low surface tension it has a highly effective wetting action.

This is obviously an important characteristic, since for maximum efficiency an antiseptic must make intimate contact with treated surfaces and their bacterial and other contaminants.

★ Presenting a Star of hope in petit mal . . .

Tridione is Abbott's newly developed synthetic drug 3,5 trimethyloxazolidine 2,4 dione which has been demonstrated clinically to have a definite inhibiting effect on petit mal myoclonic and akinetic seizures in epilepsy. Tridione is indicated in the treatment of petit mal myoclonic and akinetic epilepsy in cases diagnosed by the typical "spike and wave" electroencephalogram or by clinical features alone. It is most effective in idiopathic epilepsy but it may be used in epilepsy due to organic brain injury if attacks of the type mentioned are present. In certain patients with mixed grand mal and petit mal epilepsy it has been effective as an anti convulsant in combination with other drugs, particularly phenobarbital. Tridione is supplied in 0.3 gm capsules and bottles of 100.

Literature will be sent on request

Correspondence

Treatment of Post-operative Pulmonary Atelectasis

SIR—In his letter (April 5 p 468) Dr M H Armstrong Davison speaks of bronchoscopic aspiration, which, all observers agree is the ideal method of treatment and which should be undertaken as soon as signs of atelectasis appear.

I cannot agree with this remark, for if generally accepted it would lead to many unnecessary bronchoscopies and would serve to encourage the neglect of the various simple procedures which are quite effective in most cases.

I fully agree with Dr Davison that atelectasis is the commonest post-operative chest complication. Its incidence depends however on many factors working together, before, during and after the operation and culminating in retention of sputum in the bronchi. Our efforts should be directed to preventing this occurring or minimizing its effects in addition to the treatment of the established condition. It is not enough to rely upon some one trick or other, in which category, incidentally, falls the method described in your annotation as a new treatment. I have always resisted the attempts to put bronchoscopic suction in a prominent place in treatment because the careless or inexperienced will thereby be encouraged to take no steps to prevent sputum retention or to establish bronchial drainage by simpler postural means. I am often asked to bronchoscope patients with atelectasis after abdominal operations in whom not the slightest attempt has been made to relieve the condition by the simple change of posture (lying flat on the side two or three times a day) and encouragement to cough. I find bronchoscopic suction is but seldom needed in these cases although it is of the greatest value after many operations upon the thorax. The use of postural coughing and other simple measures is mentioned in only the three last lines of Dr Davison's letter and is having their place. They form the bed rock of management. Moreover although in expert hands bronchoscopic suction is no great burden and is effective in unskilled hands and when the patient is a child or of a difficult build it may be far from a simple procedure or a light burden.

The method of injecting water through the wall of the trachea is an unnecessarily unpleasant way to provoke coughing. If it is desired to start a fit of coughing by the irritation of water in the trachea why not use the large hole provided by nature—that is the laryngeal aperture—instead of puncturing the trachea? A curved laryngeal cannula would be just as effective—I am, etc.

LONDON W 1

R C BROCK

Orbitotomy

SIR—Mr H B Sallard's article (March 29 p 408) favouring the more generalized use of the Krönlein operation rather than the transfrontal route advocated by the late Dr Walter Dandy must appeal to those interested in the surgery of the orbit. Although Dandy's justification is not to be accepted as a *bona fide* comment for it was based on an assumption that a small incision precluded recognition of the true distribution of a lesion, there is much to be said in favour of the approach as possibly some modification of it. Nevertheless, Sallard's proposal calls for some further consideration. It should be remembered that the aesthetically result of the Krönlein operation is not the least of its merits and is hardly supposed to be a time-consuming procedure in cases in which the lateral

approach to the orbit has been carried out by highly reputable ophthalmic surgeons. My usual experience of the result is that much is to be desired, in so far as the final appearance is concerned.

An approach based on modification of both methods seems to offer much. In fact for the last two years I have operated through the scalp incision of Dandy's procedure, but have avoided the reflection of an osteoplastic flap. The scalp having been reflected the temporal muscle is turned down from the crest. A perforation is made from the temporal fossa into the orbit and the defect extended by means of nibbling forceps, to produce a combined cavity consisting, if necessary, of the orbit, the middle fossa and the anterior fossa. By such means a very extensive decompression is permitted. This operation has been found applicable to all forms of orbital exploration, more especially is it of value for the extensive relief it affords in a case of exophthalmic ophthalmoplegia.

As one may appreciate from the operative sketches, the somewhat facetious designation of the exposure as the "pawnbroker operation" will appear appropriate. I am indebted to Dr S L S Schwarzwald for the drawings—I am, etc.

LONDON W C 1

HARVEY JACKSON

The Revolution in Anaesthesia

SIR—Times have changed but still how often does this occur? A patient made stuporous with scopolamine and 'omnupon' is brought to the anaesthetic room, and after his throat has been sprayed with a solution of cocaine he is rendered completely unconscious by means of an intravenous barbiturate. The next few minutes disclose a scene of bustling activity. An endotracheal tube is inserted and this tube or the patient's face is attached firmly to that particular form of anaesthetic apparatus favoured by the anaesthetist. Cyclopropane is next administered and the patient barely breathing but still indissolubly linked to the machine, is taken into the operating theatre. A short time elapses till the surgeon complements the anaesthetist on the quiet relaxed operation field. An audible sigh of relief is heard. If on the other hand the

remark 'He's still a bit tight, doctor' is passed, how quickly a shot of tubarine secures the desired result, while the reply 'He's a very resistant type' satisfies honour, but none marvels at the miracle of what the human body can withstand. Several hours later the patient is just sufficiently conscious to be told that his operation is over, and he sinks once more into the twilight of that half-world known as 'recovering from the anaesthetic'. He does recover and reaches convalescence, often without complications, yet none wonders at the miracle. Possibly the picture is overdrawn but if it is a caricature the implications are nevertheless true.

We use to-day powerful agents which have revolutionized anaesthesia. Is it strange therefore to affirm that when they are used the whole conception of anaesthetic administration must also be revolutionized? Every phase of modern technique affects the respiratory act either centrally or mechanically. The anaesthetist must breathe for the patient, and the old conception that as long as the patient was breathing everything was all right must be forgotten and a new approach substituted. The moment these drugs and these methods are used the anaesthetist is wholly responsible for the gaseous exchange in the lungs of his patient and hap what hap *there must be no anoxia*. This can only be assured by the constant and intelligent manipulation of the rebreathing bag of a sound closed circuit. Till this is realized, shock, ileus, post-operative vomiting, and many other complications will always occur.

The day of heavy premedication has passed, for with the advent of the intravenous barbiturates the terror of induction has been removed and the slow recovery of consciousness and the essential reflexes consequent on the production of pre-operative peace, should now never be seen. Minimal premedication given at the right time is all that is required nowadays.

Cribe's theory of shock is now outmoded, it has been replaced by the solid biological fact that so long as blood loss is made good and provided that there is no anoxia with few exceptions the lighter the plane of anaesthesia the more readily can the neurovascular mechanism of the body withstand the onset of shock. It is sufficient, therefore, to maintain the patient in a light first-plane anaesthesia by the judicious use of the intravenous barbiturates, supplemented when necessary by the exhibition of a minimal quantity of cyclopropane, while relaxation is secured by the addition of *d* tubocurarine chloride. When these three drugs are used in combination they potentiate each other in a remarkable way, consequently toxic after-effects are greatly minimized but there must be no anoxia.

Anaesthesia conducted on these lines, no matter how severe the operation, will present a patient who coughs on the table and will often speak, one who on being returned to the ward is able to sit up immediately and is fully co-operative within half an hour. After this if he is nursed in a steam tent and an adequate fluid intake is assured—by the intravenous route if necessary—the bronchial secretions are kept fluid, with the result that coughing, with the wound area adequately supported, is productive and post-operative complications are avoided.

These few observations result from the experience in the use of *d* tubocurarine chloride over a period of two and a half years—I am, etc.

Liverpool

JOHN HALTON

Anaesthesia for Caesarean Section

SIR—The recent discussion on anaesthesia for caesarean section at the Royal Society of Medicine reported in your issue of April 5 (p 463) gives the impression of undiluted and almost unchallenged spinal, epidural, or caudal anaesthesia as being the method of choice. If this is so I feel that it is unfortunate and should not be left uncontested. The various speakers pointed out the disadvantages, such as the need for taking readings of blood pressure during operation, the not infrequent necessity for stimulants and the fact that it was not suitable for certain types of case, but insufficient stress was laid upon these disadvantages and the effect upon the patient was barely mentioned.

It must be admitted that an experienced anaesthetist can make a success, surgically speaking, of practically any type of anaesthesia one likes to mention. There is no onus on an obstetrician to make himself familiar with spinal anaesthesia in its various techniques, but there is, I would suggest, every

onus upon him to familiarize himself with the details of local anaesthesia. This was referred to by Mr C Macintosh Marshall and Prof Chassar Moir, but it was not sufficiently emphasized that this can often be a life-saving method. It is applicable either alone or with the addition of inhalation or intravenous anaesthesia for any and every case in which this operation is required, and in those in which the patient's condition gives rise to anxiety it is very often the only type of anaesthetic which should be used. If this were more widely recognized a considerable saving of life could undoubtedly be effected.

Its disadvantages lie only in a little added discomfort to the mother and the distaste many of us have for operating upon a conscious patient. The former can be largely avoided by careful handling and good technique, the latter by the use of inhalation anaesthesia in addition, which is, I believe the real method of choice. It is, however, very hard to better the results obtained from the point of view of both patient and surgeon by a sequence of gas, oxygen, and chloroform, followed after delivery of the child, by a little ether or what you will given by a competent anaesthetist—I am, etc.

London W 1

F NEON REYNOLDS

SIR—The recent interest in this subject at the Royal Society of Medicine (April 5, p 463) and Dr T C Gray's article on the use of *d* tubocurarine in caesarean section (April 5, p 444) will no doubt result in many conflicting opinions. While it is encouraging to read of dissatisfaction with the older method, it is disappointing to see so little support for the use of local anaesthesia. The only objection appears to be that it is unpleasant for the patient, and even so great an advocate as Mr C Macintosh Marshall refers to ameliorating the rigours of this method. In my view the unpleasantness is greatly exaggerated, chiefly by those who have used the method only a few times and who have discarded it after the initial disappointments which inevitably precede the attainment of a satisfactory technique.

Failure is usually due to one of two reasons. The first mistake is to expect too much from local anaesthesia alone. In the lower-segment operation it is practically impossible to deliver painlessly a head deeply engaged in the pelvis without the aid of some additional anaesthetic. Closing the abdomen may also be painful if the operation has not been completed in reasonable time and the effect of the local anaesthetic is wearing off. Both of these disadvantages may be met by the addition of gas and oxygen when necessary. The amount required is minimal, and a high proportion of oxygen can be given, because adequate relaxation should be obtained from the local anaesthetic. The second mistake concerns the actual technique. A considerable amount of deep "fanning out" of the injection is necessary in the suprapubic region. This is where most of the discomfort is felt, and it is aggravated by the pressure of the Doyen retractor. Needless to say the injection is greatly facilitated by the use of a continuous action syringe. The use of a sucker will minimize the painful swabbing of the peritoneal cavity.

The psychological approach to the patient is also important. Conversation and an explanation of what is happening are a great help, and it should be remembered that most operations are extremely hard. The use of 'omnupon' and scopolamine immediately after the birth of the child undoubtedly has a retrograde amnesic effect.

In this unit local anaesthesia has been used a great deal although it was discarded temporarily after the first few attempts for the reasons given above. It is now used more than any other method, but only with the object of delivering the baby entirely with local anaesthesia. After this, although the operation can be completed without further anaesthesia, there is no reason to withhold gas and oxygen, and it is usually given.

If this combined method is planned deliberately, and the addition of gas and oxygen after the birth of the child is regarded not as a "failure of local anaesthesia" but as an essential part of the technique, there should be no need to look for other methods involving complicated apparatus—'aided' respiration, foetal narcosis, and the constant watch for sudden collapse of the mother—I am, etc.

North Herts Maternity Unit

D W JAMES

Co-operation of Obstetricians and Paediatricians

SIR,—Reference has been made in recent numbers of the *Journal* to the desirability of obstetricians and paediatricians co-operating in their joint interest in the newborn infant. I should like to emphasize the value of such an experience in the light of the practice in the Belfast Medical School.

Every month the obstetricians and paediatricians of the maternity hospitals in Belfast meet to review the obstetric and paediatric problems of the previous month. The audience includes, in addition to the pathologist, anaesthetist, obstetric and paediatric registrars and tutors, senior and junior R.M.O.s and the appropriate members of the nursing staff. Representatives of the Ministry of Health and of the Belfast Corporation Maternity and Infant Welfare Department also attend. The programme includes statistics of the number of births, proportion of caesarean and forceps deliveries, etc., data relating to maternal and infant mortality and morbidity, as well as details of stillbirths and neonatal deaths. Discussions take place on incidents of special interest and questions are answered by the obstetrician and paediatrician in charge, with reports from the pathologist. Following this general review there is always time for discussion on one or more selected topics (sometimes presented by one of the registrars or tutors), often based upon an analysis of statistics obtained from the hospital records.

The value of this meeting is obvious, as obstetricians and paediatricians learn something of the problems as seen by the other. The sustained interest of those who attend regularly month after month has been sufficiently encouraging to make the meetings a recognized feature of the Belfast Medical School. The project owes its inception to the inspiration and enthusiasm of Prof. C. H. G. Macafee—I am, etc.

Belfast

F. M. B. ALLEN

Diphtheria in an Immunized Community

SIR—I have read with great interest the articles in your issue of March 22 on outbreaks of diphtheria in a highly immunized community and in adults. I have observed since 1941 in Italian populations an increase of diphtheria in adults in comparison to the child morbidity, and since then the same phenomenon has been described in nearly every country in Europe and elsewhere. But I was surprised not to find any mention of the method of restoration of diphtheria immunity in adults and vaccinated children described by G. Bousfield (*Journal* June 16 1945, p. 833). We have tried the oral administration of toxoid in adults (in Milan and Naples) and have obtained with the vaccine we have prepared better results than the Bousfield ones: one 100-Lf tablet daily for seven days was sufficient in more than 90% of the adults to provoke a very striking increase of antitoxin in the blood serum after 20 to 25 days (in many cases from <0.02 unit to more than 2 units). After these results it is difficult to exclude *a priori* the possibility of immunizing also small children by this method or some modification of it, and we have undertaken experiments in this direction. But it is certain that a new weapon against diphtheria in adults is already in our hands, and we should not forget to use it largely—I am, etc.

Naples

E. CARLINFANTI

Arsenical Encephalopathy

SIR—A case of arsenical encephalopathy with which I had to deal in 1938 showed the typical signs mentioned by Dr J. M. H. McMurray (March 22 p. 388)—headache developing in an Indian after the third intravenous injection of N.A.B. followed by convulsions and death within 48 hours, with high terminal temperature.

But this case differed from those of Dr McMurray and from that mentioned by Drs G. Hipps and R. Goldberg (March 8, p. 296) in that the patient was a congenital syphilitic. Before coming to this country he had undergone courses of treatment with myosalvarsan and bismostab intramuscularly so it would seem that it is the intravenous route of arsenical therapy which is the factor in the causation of encephalopathy—I am, etc.

London SW 1

J. STUART HENSMAN

International System of Weights and Measures

SIR—May I plead with Dr J. M. Hamill to cease advocating the substitution of the title 'International System of Weights and Measures' for the 'metric system'. In his useful article (April 5, p. 460) Dr Hamill argues that because there is no simple metrological relationship—that is, no whole-number relationship—between the metre and the kilogram and litre these last two are no longer part of the metric system. But there is a historical relationship, and verbal precision is satisfied, for the title 'metric system' is an example of that much used figure of speech which grammarians call a metonymy.

For some rapid estimations in engineering if not in medicine, the relationship between the metre and the kilogram and litre is close enough to be of help. The difference of 28 parts in one million (I prefer the British Standards Institution figure to Dr Hamill's) is not great enough to destroy altogether the relationship originally intended.

I write feelingly because I advocate the standardization of the metric system in aviation. In March, 1946, I adopted the metric system as the primary system of weights and measures in my paper *Aeronautics*. The system has been making progress in aviation. The International Civil Aviation Organization (formerly P.I.C.A.O.) has adopted it for all its publications though it still gives the British Imperial equivalents. British airline companies use it as well as papers on aviation read before the learned societies. But the way of standardization is hard, especially in view of the idiot opposition of Government departments. It would be made even harder if in place of the familiar name which is historically and grammatically correct and is brief and definite, we were to try to impose an unfamiliar, indefinite and clumsy name—I am, etc.

London W C 2

OLIVER STEWART

Editor *Aeronautics*

Dirty Milk Bottles

SIR—Dr J. H. Wildman's comments on this subject (March 29 p. 425) ignore the fact that where there are no canteen and washing up facilities milk bottles cannot be washed at schools. The lack of facilities for hand washing and even more hand drying (one towel for 30–40 children changed twice weekly is a typical provision in my area) makes the teaching of hygiene a farce.

Doctors associated in any way with schools could greatly assist the efforts made by parents and teachers to remedy this situation if having informed themselves of the lavatory and hand washing facilities available whether these are a Church or education authority responsibility, they would refuse to accept our present shortages as a reason for all deficiencies. For more than twenty years this situation has frustrated teachers and distressed parents and children. The time has come for doctors to help in the struggle for an opportunity for children to acquire practical habits of hygiene—I am, etc.

Farnham Surrey

NORA M. JOHNS

24-hour Day

SIR—A simple plan for doctors to maintain a 24-hour telephone service in the absence of anyone to take the messages would be the installation of a small recording unit which could be switched on in place of the telephone when the house is left, and which only comes into operation when a call is attempted.

I suggest that these units could be made using the magnetized steel tape method which after the messages have been read could be rubbed out and used again. Thus anyone wishing to call the doctor when he is out would hear a preamble from an incorporated record such as 'Doctor — is out. You will have two minutes to deliver your message which will be recorded. Please start with the patient's name, age, and address'. The apparatus would soon repay its cost as a part-time secretary could just come in for an hour at stated times to put the messages into writing. For the use of callers a pad and pencil could be provided in the porch—I am, etc.

Winsley Sanatorium near Bath

E. S. SHORT

Obituary

S MONCKTON COPEMAN, M.D., F.R.S., F.R.C.P.

We regret to announce the death on April 11 of Dr S Monckton Copeman at the age of 85. Dr Copeman has his place in medical history on account of his introduction of glycerinated lymph in vaccination against smallpox. This lymph was officially adopted in 1898 and has been in general use since then in this and in other countries. Dr Copeman's Milroy lectures, in which he described his work under the title of

"The Natural History of Vaccinia," were published in the *British Medical Journal* of May 7, 14, and 21, 1898.

Sydney Arthur Monckton Copeman was the eldest son of the Rev Canon A C Copeman, and was born at Norwich on Feb 21, 1862. He was educated at King Edward VI School

in that city and at Corpus Christi College, Cambridge, where he was a scholar, exhibitor, and prizeman. After obtaining second class honours in the Natural Science Tripos in 1882, he received his medical training at St Thomas's Hospital. He proceeded to the M.D. Cambridge in 1890, and was elected F.R.C.P. in 1899. After qualification he was assistant lecturer on physiology and morbid histology at St Thomas's. In 1891 he became a medical officer to the Local Government Board, and in the same year was one of

the founders of the Medical Research Club. His papers on the relationship between variola and vaccinia were published in the *Proceedings of the Royal Society* and his reputation established by these and his work on glycerinated lymph led to his election as F.R.S. in 1903. He received the Buchanan gold medal of the Royal Society in 1902, and other distinctions that came his way in that period were Cameron Prizeman of the University of Edinburgh in 1899, and Fothergillian Gold Medalist of the Medical Society of London in the same year. Among his early papers was one on the specific gravity of the blood in disease and another on haematoporphyrin in urine. He was the author of many reports on public health matters and contributed to the *Encyclopaedia Britannica*.

Copeman had a long and distinguished career in the public health services in this country and visited many parts of the world in connexion with investigations carried out on behalf of Government departments. In the war of 1914-18 as lieutenant-colonel, Copeman was in charge of the Hygiene Department of the Royal Army Medical College. He played an active part in many medical societies and organizations. He was, for example, Research Scholar and Special Commissioner of the British Medical Association, a member of the Council of the Royal College of Physicians, a member of the Faculty of Medicine, and chairman of the Board of Studies in Hygiene of the University of London; examiner in public health and in forensic medicine and toxicology in the University of Bristol; examiner in public health, Royal College of Physicians and the University of Leeds. After he retired from the service of the Ministry of Health in 1925, Copeman began to play an active part in the affairs of local government. For many years he was a member of the London County Council. He was also a member of the Hampstead Borough Council and chairman of its Public Health Committee.

He joined the British Medical Association in 1888, and was secretary of the Section of Public Medicine in 1892. At the Annual Meeting of 1910 he was vice-president of the Section of State Medicine. He was at one time chairman of the Hampstead Division, and took part in the central work of the Association as a member of the Science Committee (1932 and 1936) and of the Library Subcommittee (1933).

Copeman was distinguished in appearance and unfailingly courteous in manner. His wide culture brought him into con-

tact with men and women in many walks of life. He married Ethel Margaret, youngest daughter of the late Sir William Board, Bt., and had a son and two daughters. His son is a consulting physician in London.

Sir Arthur MacNalty writes

The death of Monckton Copeman at the advanced age of 85 removes one of the few survivors of the medical staff of the Local Government Board, who accomplished great things in the organization of public health in the nineteenth century and early years of the present century. Copeman, after a distinguished career at Cambridge and St Thomas's Hospital, became a medical inspector of the Local Government Board in 1891 and all his active medical life was spent in the service of that department and, subsequently, as a medical officer of the Ministry of Health. His discovery of the value of glycerine in destroying pathogenic organisms associated with calf lymph, the use of glycerinated calf-lymph in vaccination, and his papers in the *Proceedings of the Royal Society* on the relationship of variola and vaccinia early established his scientific reputation and for this work he was made F.R.S. in 1903. The use of glycerinated lymph abolished arm-to-arm vaccination and made vaccination a much safer and simpler operation. For this also Copeman deserves to be remembered.

Although Copeman served on many departmental committees his real interest lay in scientific research, and his alert mind fertile in new ideas, was directed to various subjects of inquiry. During his latter years at the Ministry of Health he devoted special attention to the cancer problem, and his report with Prof. Major Greenwood on *Diet and Cancer* with special reference to the incidence of cancer upon members of certain religious orders opened a new field of inquiry. He was a member of the Ministry of Health's Departmental Committee on Cancer, where his advice and ripe experience proved of much value. He was also a pioneer in immunization against diphtheria in this country. Endowed with untiring energy and enthusiasm, he found time in a busy official life to develop Army hygiene during the war of 1914-18. Keenly interested in natural history, he was a member of the Council of the Zoological Society and did much to improve its work on scientific lines.

Copeman had a generous and kindly disposition. A man of many interests and of wide culture, he was a delightful companion and I learned much from him during the years that we shared a room together in the Ministry of Health. He wrote to me frequently in recent years, and his letters do not show how well he kept himself informed of modern progress in medical research.

The life of Monckton Copeman was devoted to the public service and to the prevention of disease, and he did much to maintain the high standard of English State Medicine.

EDWARD J M WATSON M.D., F.R.C.P.

Dr Edward John Macartney Watson died at his home in Dublin on March 22 at the age of 74 after only a few days' illness. A son of the late Sir William Watson, managing director of the City of Dublin Steam Packet Co., he was educated at Eton and before entering Trinity College, Dublin, in 1895 he studied engineering at Trinity College, Cambridge. There he gained his blue in athletics and was a member of the team which toured Canada and the U.S.A. In 1900 he graduated, and in 1906 he became a Fellow of the Royal College of Physicians in Ireland. Shortly after graduation he was appointed assistant physician and anaesthetist to Sir Patrick Dun's Hospital, where he had been a student, and in the same year he was put in charge of the x-ray department, a post which he held until his death. For some years he also held a similar appointment at the Richmond Hospital. In 1923 he became, in addition, physician in charge of the x-ray department at the Adelaide Hospital. During the first world war he served as radiologist to Dublin Castle, Red Cross Hospital and in France with the R.A.M.C. on the staff of the 83rd (Dublin) General Hospital. Subsequently he was appointed radiologist to the Ministry of Pensions Hospital at Blackrock, later on to Leopardstown, Co. Dublin, where he had attended as

four days before his death. Shortly after the war he married Maureen, only daughter of the late T O Read and Mrs Read of Roscrea.

Dr Watson was a vice president of the Radiological Society of Ireland, and throughout his professional career he practised general medicine in addition to radiology. Like many of his early fellow workers he suffered much from x-ray burns, necessitating several operations, but he bore his disabilities uncomplainingly. Edward Watson, though he never paraded them, was a man of deep religious convictions, and his charity was, like all his actions, unobtrusive. He was always interested in Church matters, and for many years, in addition to various parochial appointments, acted as medical referee to the Representative Body of the Church of Ireland. He served on the committees of several philanthropic institutions, in which he took a lively interest, and to the success of which he contributed in no small measure by a calm and logical outlook, characteristic of the man.

His non-professional interests lay to a large extent in the field of athletics, and for many years he had been an active force both in the Dublin University Central Athletic Association and the Rugby Football Club. As a Commissioner of Irish Lights since 1923, nothing short of incapacity was allowed to interfere with his attendance at the weekly meeting of that body, which is responsible for all navigational apparatus on the Irish coasts. One of his greatest pleasures was to take part in the annual cruise of inspection around Ireland. He was indefatigable in the discharge of the duties involved, which often entailed hazardous landings in heavy seas, and for which he was well qualified by his engineering training and family association with shipping. A skilled woodworker, in the early days he constructed many ingenious and beautifully finished articles of x-ray equipment.

Though one of the most retiring of individuals, Edward Watson had a wide circle of friends, and if any evidence of his popularity was needed, ample proof was forthcoming in the very large attendance at a memorial service held in Christ Church, Leeson Park, where he had worshipped since childhood.

ERNEST WATT OBE, MD FRCP Ed

Dr Ernest Watt, for many years a medical officer of the Department of Health for Scotland, died at his home in Edinburgh on March 26 at the age of 71. He had a most distinguished academic career at Glasgow University, graduating MB ChB in 1897, MD in 1901, BSc (Public Health) in 1912, and DSc in 1917; he took the DPH at Cambridge in 1905, became a member of the Royal College of Physicians of Edinburgh in 1916 and was elected to the fellowship in 1931. After service as house-physician and house surgeon at the Victoria Infirmary Glasgow he held resident posts at the City of Glasgow Fever Hospital and the Glasgow Royal Maternity Hospital. Next came a short spell in general practice, after which he returned to hospital work as resident physician and bacteriologist to the Ochil Hills Sanatorium and later, physician-superintendent of the Middle Ward of Lanarkshire Hospital. Successive appointments followed as senior assistant to the county medical officer of Lanarkshire, MOH of the Burgh of Partick and chief tuberculosis officer for the County of Durham. While working in Partick he acted as assistant to the professor of forensic medicine and public health Glasgow University. In 1913 he was appointed tuberculosis medical inspector to the Local Government Board for Scotland continuing the same duties as a medical officer in the Scottish Board of Health and later in the Department of Health for Scotland until he retired in May, 1941. In 1939 he was awarded the OBE.

Widely known in Scottish medical circles Ernest Watt's opinion was freely sought on all matters connected with tuberculosis a subject on which his knowledge was extensive and profound. He was no narrow specialist however and many of his professional associates profited from his mature experience in general public health. He had wide cultural and scientific interests and for many years he was a member of the Astronomical Society of Edinburgh of which for a year he was vice president. All his academic attainments, experience, and interests apart it is the man himself who will be best remembered. Unassuming, patient, and imperturbable at all

times, his gentle, kindly disposition made him intuitively seek the good points in his fellow men, though he was not unaware of the failings of those who fell short of his own high standards. He will be greatly missed by all who had the privilege to know him.

'F S' writes Dr Ernest Watt was one of a small band of medical officers of the former Scottish Board of Health under the inspiring leadership of the late Sir W Leslie Mackenzie. The domain in which, in addition to medicine, his knowledge was outstanding was science, pure as well as applied. Among many other evidences the high standard of his attainments there in was well illustrated in the treatise written by him in 1925 in collaboration with the late Dr Lewis D Cruickshank and entitled *An Interim Report on Artificial Light and X-Ray Therapy*. In the more strictly medical sphere tuberculosis was the subject in which he specialized, and in which he served so acceptably as an official consultant. As a churchman his interests and his influence were life long.

If he could be numbered among the most highly qualified and the most scientifically minded, certainly he could also be accounted as the most modestly unassuming of all the many medical men whom the writer has met and with whose friendship he has been privileged. Especially conspicuous in his character was candour. Anything of the nature of duplicity or of subterfuge was alien to him.

ENEAS K MACKENZIE, MD

Many members of the profession learnt with regret of the sudden death, at the age of 65, on March 27, of Dr Eneas Kenneth Mackenzie, of Tain. Educated at Inverness Royal Academy he studied medicine at Aberdeen University where he graduated MB ChB in 1906, proceeding MD in 1909. For over thirty years he practised in Tain. He was a man of great character and outstanding ability. He gave his patients of his best and was much beloved and greatly respected. Dr Mackenzie took a keen interest in the organization of the medical services in the North of Scotland and in the development of the Royal Northern Infirmary, Inverness. A Highlander with more than the usual amount of Highland pride he contributed in no small measure to the reputation which the Highlands and Islands Medical Service so richly deserves. He was particularly interested in obstetrics, in which he was widely recognized as an authority. He had an orderly mind and differed from the great majority of doctors in that he enjoyed keeping meticulous records of his work. He was intolerant of authority and when roused expressed himself with characteristic Celtic fervour. He had, too, oratorical gifts of a high order. Yet he was the most humble of men and inspired affection in a remarkable degree.

He was appointed a member of the Medical Advisory Committee to the Secretary of State for Scotland at its inception. For two years he was chairman of the Highlands and Islands Subcommittee of the Scottish Committee of the British Medical Association succeeding that other well known Highland practitioner Dr J B Simpson, late of Golspie. Eneas Mackenzie had held office as president of the Branch as chairman of the Panel Committee and as an examiner for the Central Midwives Board for Scotland. For eighteen years he was chairman of the Ross and Cromarty Insurance Committee. His capacity in other spheres was recognized by his appointment as an honorary sheriff substitute for the county.

For some years he had been in indifferent health and it was difficult for a man of his temperament to take things quietly. He died as he desired while still actively engaged in practice. Dr Mackenzie is survived by his wife and two sons. His elder son is a lieutenant colonel in the Indian Medical Service the younger a dental surgeon-lieutenant in the Royal Navy.

The British Legion Village is to establish a nurses' home in the centre of Colchester for nurses employed at Nayland the British Legion sanatorium for ex-Service women and dependants which lies nine miles outside the town. Nayland will be the first sanatorium in the country to provide such a facility for its staff. Transport will be provided to convey the nurses between the home and the sanatorium.

Universities and Colleges

UNIVERSITY OF OXFORD

Election of Two Members of the Board of the Faculty of Medicine by the General Medical Electorate

An election of two members of the Board of the Faculty of Medicine will be held on Wednesday, June 4. The members elected will come into office on the first day of Michaelmas Term 1947, and will hold office, the senior for two years and the junior for one year from that day. The General Medical Electorate consists of all Oxford graduates in medicine who are members of Convocation. The Board of the Faculty of Medicine includes two members elected by the General Medical Electorate who must be members of that body and of whom one at least must be a person engaged in teaching one or more of the clinical subjects of the Faculty. Nominations of duly qualified candidates for election will be received by the secretary of Faculties at the University Registry, Oxford, up to 10 a.m. on Wednesday, May 14. Each nomination must be signed by six members of the General Medical Electorate, and no candidate will be eligible whose nomination has not been received by that date.

The Electors have awarded the George Herbert Hunt Travelling Scholarship to Selwyn Francis Taylor, B.M., M.Ch., of Keble College.

UNIVERSITY OF CAMBRIDGE

Sir Howard Florey, M.D., F.R.S., professor of pathology in the University of Oxford, will deliver the British Association's Radford Mather Lecture in Regent House, on Friday, May 2, at 5 p.m. His subject is 'Penicillin and other Antibiotics'.

UNIVERSITY OF LONDON

A course of six public lectures on 'Cell Physiology and Pharmacology' will be given by Dr J. F. Danielli in the Department of Pharmacology of University College on Fridays at 5.15 p.m., from April 25 to May 30. Admission is free and without ticket.

University College Hospital Medical School

A revision course of three weeks' duration in preparation for the examination for the Diploma in Anaesthetics will be held at University College Hospital Medical School beginning on Monday, April 21. The course is comprehensive in scope, including anatomy, physiology, applied physics, and pharmacology and is limited to 25 members. The fee is £21 inclusive. Applications to join should be addressed to the secretary, University College Hospital Medical School, University Street, W.C.1.

UNIVERSITY OF SHEFFIELD

Profs C. P. Beattie and C. H. Stuart Harris have been appointed representatives of the University at the fourth International Congress of Microbiology to be held at Copenhagen from July 20 to 26.

UNIVERSITY OF DURHAM

Prof. G. Grey Turner, M.S., F.R.C.S., will give the first Rutherford Morrison Lecture in the Royal Victoria Infirmary, Newcastle upon Tyne, on Thursday, May 29, at 5.15 p.m. His subject is "Rutherford Morrison and his Achievement in Surgery".

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Election of Professors and Lecturers

The Council of the College invites applications for election to the office of Hunterian Professor, Arris and Gale Lecturer, Arnott Demonstrator and Erasmus Wilson Demonstrator for the ensuing year. The twelve Hunterian Lectures are delivered by Fellows or Members of the College. The three Arris and Gale Lectures are on subjects relating to human anatomy and physiology, the six Arnott Demonstrations on the contents of the Museum, and the six Erasmus Wilson Demonstrations on the pathological contents of the Museum. Applications in writing must reach the assistant secretary of the College (Lincoln's Inn Fields, W.C.) by April 28. Candidates for the Hunterian Professorships and the Arris and Gale Lectureships are requested to submit with their applications twenty copies of a synopsis of approximately 500 words describing the subject matter of their proposed lecture. In the case of Hunterian Lectures the Council is prepared to consider applications for either a series of lectures or a single lecture. Lecturers will be appointed subject to the condition of giving the College first refusal of publishing their lectures in the *Annals of the Royal College of Surgeons*.

Practical demonstrations in anatomy applied physiology and pathology have been arranged by Profs F. Wood Jones, John Beattie, and R. A. Willis, beginning on Monday, July 7, and continuing until Tuesday, Sept. 30, from 10 a.m. to 1 p.m., and from 2 p.m. to 3.30 p.m. daily. The fee is £21, and the closing date for

applications is May 12. The demonstrations will be open to those attending the main course of lectures to be held in July and September and will be limited to 40 students, preference will be given to those unable to obtain practical instruction elsewhere and to ex-Servicemen. Applications, accompanied by a cheque for £21, should be sent to the assistant secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2.

Medico-Legal

REMUNERATION OF AGENCY NURSES

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The Nurses Act, 1943, made "nurses co-operations" subject to licensing and inspection by local authorities. Section 8 (2) provides that in licensing an agency for the supply of nurses a local authority may attach such conditions to the licence as they may think fit for securing the proper conduct of the agency. In renewing the licences in the London area this year, the London County Council attached a number of new conditions. These prohibited an agency from charging a client more than the rates laid down in schedules attached to the licence and also from removing a nurse from service without giving reasonable time to replace her.

Mr Lewis Miller the proprietor of the London and District Nursing Association, which supplies about 400 nurses a year, appealed to the Clerkenwell Petty Sessions on the ground that the new conditions were illegal. His counsel, Mr G. R. Blarico White K.C., pointed out in the course of his argument that if the salary limits were valid a trained nurse of fifteen years' experience would get £5 3s. 10d. a week against the £6 1s. earned by a bricklayer's labourer. Mr C. Erskine Simes K.C., for the Council, said that it was merely imposing a scale which had been agreed upon by the employees and representatives of various nursing bodies and by the Minister of Health, and which was a reasonable scale. Mr Bertram Reece the stipendiary magistrate, giving judgment on March 31, said that in his view "only a temporary view"—the conditions were *ultra vires* of the Act, unreasonable, and against the public interest. He allowed the appeal and awarded 125 guineas costs against the L.C.C.

The issues in this case affect about 20,000 nurses, half of them in London, and raise fundamental questions concerning the proper place of agencies in the system of staffing hospitals up and down the country. Comment would be out of place until the appeal has been finally settled by the High Court, the Court of Appeal, or the House of Lords, all of which are open to the parties at successive stages.

A DEATH FROM PETHIDINE

The Westminster coroner inquired on March 28 into a death due to an overdose of pethidine (the hydrochloride of the ester of 1-methyl-4-phenylpiperidine-4-carboxylic acid). A clerk of 44 was found unconscious in a Paddington hotel and died soon afterwards. Four bottles of 3/4 gr. (50 mg.) tablets from which 54 tablets were missing, were found in his room. Dr G. Roche Lynch said in evidence that this was the first fatal case of pethidine poisoning he had met. The drug has an action similar to that of morphine. As it was discovered to produce addiction in some cases it was placed under the Dangerous Drugs Act in February last.

The Services

Lieut. Col. W. H. Crichton, C.I.E., I.M.S., has been appointed a Commander of the Order of Orange Nassau (with swords) for services when Director of Public Health and Welfare with 21 Ar. Group, B.L.A.

NAVAL MEDICAL COMPASSIONATE FUND

A meeting of the subscribers to the Naval Medical Compassionate Fund will be held at the Medical Department of the Navy, St. James's Street, London, S.W.1, on Friday, April 25, at 3 p.m. to elect six directors of the fund.

Outbreaks of Smallpox

Fifteen separate introductions of Asiatic smallpox occurred in England and Wales during 1946. Fortunately, on each occasion vaccination and surveillance of contacts brought the disease under control rapidly, and only 40 persons became infected during the year. In mid-February, 1947, after an interval of seven months, the disease again appeared, and since then 33 cases have been notified (15 at Grimsby, 2 at Stepney 7 at Scunthorpe, 1 at Doncaster, and 8 at Bilston). The disease was introduced from an unknown source into a common lodging house at Grimsby Lincs, when two old men sickened on Feb 13 and 16. Subsequently 13 further cases arose, all in the direct line of contact with the original two cases. One was a man who had spent the night of Feb 16 at the common lodging house, and subsequently developed smallpox at his home in Grimsby. Two members of the staff of the public health department (a sanitary inspector and a disinfecter) both of whom had been concerned with the disinfecting of the common lodging house, developed smallpox while living at home. With the exception of these three all the secondary cases occurred among contacts either at the common lodging house (4) or in the ward of the public assistance infirmary (6) into which the original patient was unfortunately admitted. The total number of cases in this outbreak was thus 15. There were 6 deaths, and the high mortality was associated with the advanced age of the persons affected and previous debilitating disease in 4 of them. The last case at Grimsby was removed on March 9, and the town is now believed to be free from infection.

It is probable that an unidentified contact from Grimsby infected an attendant at a hostel for seamen at Stepney. Fortunately this man was admitted to a general hospital early in the disease and there infected only one patient. Since the removal of this secondary case on March 21 no further cases have been notified in the London area.

The disease next appeared at Scunthorpe, 28 miles from Grimsby. The first patient resided in a common lodging house where two contacts who had absconded from surveillance at Grimsby were staying. Initially, this man was diagnosed as a case of varicella and admitted to an infectious diseases hospital. In the second generation 6 cases have been notified, the first developing the rash on April 4. They include a doctor vaccinated in infancy only and an unvaccinated nurse, both of whom were attending the patient, the others were residents at the common lodging house. Five contacts have absconded from this lodging house while under surveillance. Their whereabouts is unknown, and they may be incubating, or suffering from smallpox.

There is no further information concerning the source of infection at Doncaster. The disease there in a schoolmaster was detected early, and prompt vaccination appears to have prevented further spread. Surveillance of contacts has now ceased.

All these cases appear to be infected with Asiatic smallpox of moderate severity. In contrast, the disease at Bilston in Staffordshire, is said to be variola minor, although it originated in India or Cairo, more probably the former. The third generation of cases (with onset April 3 to 9 rashes April 5 to 10) numbers 5 one of whom, a woman aged 79 died during the prodromal period. The initial case and the second generation (2) although confidently diagnosed chickenpox until variola virus was isolated in the laboratory remained confined to their beds from the onset and the infection is believed to be limited to a circle of relatives and friends in three households. The clinical picture has been misleading. In two of the patients there were less than half a dozen lesions and the illness is described as being like 'influenza with a few spots'.

Because of the difficulties in diagnosis and, more important, because ambulant cases of variola minor are sometimes relatively numerous and if missed may bring about a wide dispersal of infection the reappearance of mild smallpox in the country should be viewed with apprehension and every effort made to detect new foci promptly. A medical officer of health should be consulted whenever there is the slightest suspicion.

At the time of going to press a further patient is under observation awaiting diagnosis at Rubery, near Birmingham.

Information received from Paris is to the effect that there were 32 cases of smallpox with 2 deaths between Feb 10 and April 2.

Food poisoning

There was recently an outbreak of food poisoning at the County Mental Hospital, Winwick Warrington. All the cases occurred

within twelve hours of one another, and the main feature was a mild diarrhoea which cleared up rapidly. No patient had a temperature above 98.8° F (37.1° C). Only four were considered ill enough for the relatives to be informed but there were two women, aged 63 and 64 who collapsed and died a few hours after the onset. The number of patients affected was 25 out of a total of 150 in a ward which is an outlying block with a kitchen of its own. This ward is not connected with the main building in which some 1,800 other patients live.

Post-mortem examination of the two fatal cases showed a remarkable degree of enteritis and the presence of an intestinal obstruction, due in one case to diverticulitis and faecal impaction and in the other to a carcinoma of the bowel. Evidently the enteritis had caused a partial obstruction to become complete with extreme inflammation above the obstruction but little abnormality below it. The cause of death was returned at the inquest in accordance with the medical evidence, as intestinal obstruction with non-specific enteritis as a contributory cause.

The fact that there was no outbreak of diarrhoea in the main building strongly suggested that the food (meat or fish, probably) was not likely to have been received in an infected condition. This was further confirmed by laboratory tests done on samples of the food still in stock from the same delivery. The infection must therefore have occurred in the ward itself and there must have been a sufficient lapse of time between the infection and the consumption of the food for enterotoxins to have been produced to a degree sufficient to account for the sudden and explosive outbreak. In any case, any organisms of the typhoid, dysentery, and *Salmonella* groups were ruled out by the negative results obtained from the examination of the stools of all affected cases. The only food to which this interval between infection and consumption could have applied was some mutton. This had been steamed the day before consumption and left overnight. A sample of this meat was retrieved from the swill and bacteriological examination showed the presence of a few unimportant organisms with a heavy infection by *Staphylococcus aureus*. The same organism was found in the bowel of the two patients who died. No septic cases were known to be under treatment at the time in the ward (they were all chronic mental cases who were up and about), and on searching for a possible source of infection it was found that a cat in the building had a post-lactational mastitis. Examinations were made and an almost pure culture of *Staphylococcus aureus* obtained. Further investigations are being made and presumably phage typing will indicate whether the staphylococci recovered from the mutton, the fatal cases, and the cat are, or are not, identical.

Discussion of Table

In *England and Wales* an increase was recorded in the notifications of diphtheria 42 and dysentery 37 and a decrease was reported for measles 515 and scarlet fever 45.

The largest decreases in the incidence of measles were Yorkshire West Riding 132, Essex 128, and Middlesex 96. No large local variations occurred in the notifications of scarlet fever.

The only change of any size in the trends of whooping cough was a decrease of 44 in Yorkshire West Riding. There was a small general rise in the incidence of diphtheria, Lancashire had 11 more cases. Dysentery was slightly more prevalent in most areas, and there was an increase of 15 in Middlesex due to the outbreak at Southall M.B., where 17 cases were recorded during the week.

In *Scotland* the only changes of any size in the trends of infectious diseases were increases in the notifications of measles 142 and scarlet fever 42.

In *Aberdeen* 89 babies have died of gastro enteritis during the past three months. The babies were nearly all bottle-fed and their symptoms were similar to those recorded in similar outbreaks in England.

In *Eire* 14 cases of typhoid were notified involving five different areas. Scarlet fever whooping cough, and measles were slightly more prevalent in Dublin C.B.

In *Northern Ireland* the notifications of diphtheria increased by 15. Notifications of whooping cough in Belfast C.B. rose by 17.

Week Ending April 5

The notifications of infectious diseases in England and Wales during the week included scarlet fever 995 whooping-cough 1,775, diphtheria 184, measles 8,343 acute pneumonia 730 cerebrospinal fever 86, dysentery 44 smallpox 2, paratyphoid 6, typhoid 8.

Medical News

Sir Alexander Fleming, F.R.S., leaves to-day (April 19) to lecture in Vienna on penicillin at the invitation of the Society of the Austrian Medical Profession and under the auspices of the British Council.

A meeting of the Tuberculosis Association will be held at King George V Sanatorium, Godalming, to-day (Saturday, April 19) at 11 a.m. At 2 p.m. there will be a discussion on "Some Complications following Adhesion Section," to be opened by Dr James Watt, Mr J. E. H. Roberts (Natural History and Treatment of Post-Operative Effusions), and Dr W. E. D. Moore (Haemothorax), at 3.45 p.m. Miss M. Sheehan will read a paper on "Employment of Tuberculous Staff."

Meetings of the Biological Methods Group of the Society of Public Analysts and Other Analytical Chemists will be held at the Royal Society of Medicine (1, Wimpole Street, W.) on Monday, April 21, and Monday, May 12, at 6 p.m. The meetings for Parts 2 and 3 of a symposium on "The Production and Care of Laboratory Animals, Part 1 of which took place on March 17. The papers to be read are as follows: April 21, Dr H. J. Parish, "Common Diseases," Mr N. T. Gridgeman, "Records," May 12, Drs J. I. M. Jones and Eric C. Wood, "Housing." A general discussion on subjects covered by the papers read at all three meetings will follow. The meetings are open to the medical profession, members of which are invited to take part in the discussion.

The annual general meeting of the Food Group of the Society of Chemical Industry will be held at the Chemical Society's rooms (Burlington House, Piccadilly, W.) on Wednesday, April 23, at 6.30 p.m., when the chairman of the group will give an address on "Some Problems of Trade Effluent Disposal."

A meeting of the Medico Legal Society will be held at 26, Portland Place, W., on Thursday, April 24, at 8.15 p.m., when a paper by Dr David R. Mace on Marriage Breakdown and Divorce (Some Aspects of the Denning Report) will be read.

The annual general meeting of the Birmingham Local Section of the Institute of Metals will be held at the James Watt Memorial Institute, Great Charles Street, Birmingham, on Thursday, April 24, at 6.15 p.m. At 7 p.m. an address will be given by Dr Neil G. Marr, on "Medical Services in the Non-ferrous Metals Industry." A discussion will follow.

The spring meeting of the British Orthopaedic Association will be held at Exeter on Friday and Saturday, April 25 and 26. At University College, Exeter, on April 25, at 9.30 a.m., there will be a symposium on "The Surgical Treatment of Tuberculosis of Bones and Joints," to which Mr G. R. Girdlestone, Mr Norman Capener, Mr M. C. Wilkenson, Mr J. P. Campbell, Mr B. L. McFarland and Mr J. A. Cholmeley will contribute. At 2.15 p.m. there will be a clinical meeting at the Princess Elizabeth Orthopaedic Hospital, when a review of Devonian orthopaedic practice by the staffs of the hospital and of the Mount Gold Orthopaedic Hospital, Plymouth, will be presented. On April 26, at 9 a.m., there will be a business meeting at the Royal Devon and Exeter Hospital and from 10 a.m. to 1 p.m. various papers will be read.

A sessional meeting of the Royal Sanitary Institute will be held at Carlisle Town Hall on Friday, April 25, at 10.30 a.m., when Dr F. H. Day will read a paper on "Dust in Domestic and Public Buildings: Its Nature and Properties."

A meeting of the Scottish Group of the Nutrition Society will be held at University College, Dundee, on Saturday, April 26, when there will be a discussion on "The Preservation Colouring and Flavouring of Foods." Members of the Food Group are invited to attend the meeting.

The first general meeting of the Kent Paediatric Society will be held at Farnborough County Hospital on Saturday, April 26, at 2 p.m., when Dr Duncan Leys will give an address on "A Co-Paediatric Service." Membership of the society is open to registered medical practitioners engaged wholly or partly in preventive or curative work among children, whether resident in county or not, including general practitioners. Applications for membership should be addressed to the honorary secretary, Dr P. Swift Paediatric Unit, Farnborough Hospital, Kent. The subscription is 10s.

The British Council for Rehabilitation (32, Shaftesbury Avenue, London W.1) is arranging a short course on rehabilitation to be held at Nottingham from April 29 to May 1. The fee of £5 includes lunch and tea each day and transport from Nottingham to the places visited. The course will include addresses on "Physical Rehabilitation," "Rehabilitation of Miners" and "Rehabilitation in an Engineering Works." Vacancies are limited and applications should be sent not later than April 19.

*The improved
tar preparation*

E.S.T.P.

BRAND (MARTINDALE)

Ether Soluble Tar Paste

Purified, decolorised, non-staining,
aromatic, maximum Tar effect

FORMULA

Ether Soluble Tar Distillate ... 15%
Zinc Oxide ... 14.0%
Starch ... 12.0%

In a special emollient base

A smooth paste easily applied. The tar component retains the essential phenolic compounds unimpaired ensuring powerful antiseptic action. All indications for Tar Treatment are indications for ESTP (Martindale) more especially infantile eczema, eczematosa generally, impetigo complicating eczematosa, prurigo, pruritus, psoriasis, pityriasis circinata, lichen planus. In 2 oz. and 16 oz. pots. Sample and literature on request.

BRIDGING THE GULF

IN ARTIFICIAL FEEDING

For more than forty years COW & GATE Milk Foods have successfully bridged that dangerous gulf in infant feeding when breast feeding is impossible or inadequate and the child's delicate digestion needs especial consideration.

Normally medical opinion in such cases directs that a baby should be introduced to artificial feeding by means of a half cream milk.

COW & GATE HALF CREAM MILK FOOD

bridges the gulf between breast and full artificial feeding. The transition period may be artificial and Cow & Gate Half Cream provides a most satisfactory means of introducing complementary feeding. Should immediate change to full artificial feeding be necessary Half Cream Food ensures a minimum disturbance of infant metabolism.

THE FOOD IS FORTIFIED BY THE ADDITION OF VITAMIN D 320 I U per OUNCE AND IRON 1 mgm per OUNCE.

Particulars of this and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request.

COW & GATE LTD
GUILDFORD SURREY

To be sure . . .

Specialisation in sutures over the last sixty years has given Johnson & Johnson a leadership which is literally world-wide. Take, for example, their Ethicon Non Borlable Catgut Sutures. These, as taken from the sterile tubes, have more tensile strength than is required to ligate the largest human blood vessel or to suture the most dense human tissue. It is interesting to record that Johnson & Johnson are Sole Agents for the new biologically inert Surgical Metal—Tantalum. Ethicon Tantalum Sutures are likely to play an important part in surgery of the immediate future.

Johnson & Johnson
(GT BRITAIN) LIMITED

Slough, Bucks

Three Plastules daily will provide 15 grains of readily assimilable ferrous sulphate and will produce optimal haemoglobin response. This small dosage has been demonstrated to be just as effective as massive doses of other forms of iron in the treatment of hypochromic anaemia.

"SULPHANILAMIDE TULLE" CREAM

In order that the doctor may have a free choice of bacteriostatic dressings, SULPHANILAMIDE TULLE Cream (Optrex Brand) is now offered to the medical profession.

SULPHANILAMIDE TULLE Cream can be used as an ointment, or applied on a sterile spatula direct to a diseased or injured area, or spread on gauze, linen, or oiled silk.

The formula is the same as that used for the emulsion in Sulphanilamide Tulle which—available only on prescription—has had continued success during the past years due to its acceptance and appreciation by doctors as a product based on the latest scientific knowledge.

SULPHANILAMIDE TULLE Cream is indicated in the treatment of burns and scalds as a primary dressing to prevent infection. It is also successful in the treatment of septic skin lesions of indolent ulcers, and for burns and scalds when infection has already occurred. The dressing when used in combination with SULPHANILAMIDE TULLE Cream need only be changed infrequently and healing proceeds rapidly without disturbance of new epithelial cells.

SULPHANILAMIDE TULLE Cream is sold in tubes and is thus maintained sterile and ready for use. The sterility and composition of each batch is controlled by bacteriological and chemical examination.

Composition—SULPHANILAMIDE TULLE Cream contains 10% w/w Sulphanilamide in Paraffin-Lanolin-Water emulsion.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Penicillin and Sulphonamides

Q—A patient with infected burns developed on the face a rash which subsided in a few days. Did the fact that she was undergoing a course of penicillin treatment automatically exclude erysipelas? Is there any clinical condition which having failed to respond to adequate penicillin therapy may respond to one of the sulphonamides? Has sulphamezathine any advantages over sulphathiazole or sulphadiazine? Is it correct that a twice weekly intramuscular injection of 100 000 units of penicillin is less effective than 20 000 units three hourly and that 200 000 units twice daily is as efficient as the three-hourly courses?

A—True erysipelas, due to a haemolytic streptococcus, could not develop during a course of injections with penicillin in adequate doses. There are many conditions more or less susceptible to treatment with sulphonamides on which penicillin has no effect. They include bacillary dysentery, non-coliform infections of the urinary tract, similar infection (for example, due to *Ps. pyocyanea*) elsewhere, including the meninges, any condition, whether sinusitis or pneumonia, due to Friedlander's bacillus, and undulant fever. The chief advantage of sulphamezathine is its slow excretion, moderate and infrequent doses thus maintain a continuous effect. It is also sufficiently soluble in urine to render the risk of obstruction remote—an advantage over sulphadiazine.

The last part of the question has recently been discussed in this column (Jan 25, p 167, Feb 1, p 207). It is impossible to answer the precise question asked here. A dose of 200,000 units produces an adequate blood level for no more than four or five hours, whether the very high level attained at the beginning of this period, with its resulting diffusion into the tissues, compensates for the succeeding period of seven hours during which the blood contains little or no penicillin can be decided only by observation in different types of case. One would certainly hesitate to rely on twelve-hourly administration if a patient's life were in danger. (See also in this issue an article at page 530 and an annotation at page 536.)

Fatal Dosage of Arsenic and Antimony Tartrate

Q—A woman of 42 took a horse 'worm powder' in mistake for a headache powder and shortly afterwards collapsed. The powder contained 4 gr (0.25 g) of arsenic and 51 gr (3.4 g) of antimony tartrate. The stomach was washed out with tannic acid solution and she made an uninterrupted recovery. What are the usual fatal doses of arsenic and of antimony tartrate?

A—Two grains (0.13 g) is commonly considered as a possible fatal dose of white arsenic, but different subjects vary greatly in susceptibility. Four grains (0.25 g) might reasonably be regarded as fatal. So far as antimony tartrate is concerned, the amount received by the patient was nearly three times the fatal dose which lies between 0.01 and 0.02 g per kilo of body weight or about 18 gr (1.2 g) for an adult. Evidently the treatment given was most effective and saved the patient's life.

Summer Prurigo

Q—A young man suffering from prurigo aestivalis develops a papular eruption on the forearms, hands and face on exposure to sunlight. Itching is severe at times. What is an effective treatment?

A—Treatment of summer prurigo is disappointing. The condition is dependent on specific sensitization to certain kinds of light or to ultraviolet rays. A general overhaul is needed with special reference to focal sepsis, gastro-intestinal function, and nutritional deficiencies. Desensitization—by graduated exposure of the whole body to natural or artificial sources of light—is sometimes partially successful. X-ray therapy, if

assisted by protective measures, gives temporary relief. Occasionally gold therapy, injection of vitamin A concentrates, or nicotinamide by mouth or injection seems to protect, without obvious reason. Applications to prevent the rays penetrating to the exposed skin are generally necessary during daylight. The most effective are petroleum jelly and a titanium dioxide preparation (after its application any excess can be removed with damp cotton-wool). A lotion containing equal parts of calamine, glycerin, and water is of use in mild cases. An ichthyol powder may subsequently be applied. These measures can also be employed in the form of 'barrier creams'. Alternatively petroleum jelly may be used with an emulsified base or ung. aquosum B.P. in equal parts. "Benadryl" has been reported as controlling urticaria due to light-sensitiveness. It would be worth trying in light prurigo.

Treatment of Heart-block

Q—A male patient aged 58 who has a resting pulse rate of 20 suffers from nocturnal feelings of suffocation. Can you suggest any effective treatment?

A—A pulse rate of 20, if it is accompanied by a correspondingly slow heart rate, is an almost certain indication of complete heart-block, probably associated in this case with a severe degree of myocardial degeneration which would be likely to cause nocturnal feelings of suffocation. Injections of adrenaline or the oral administration of ephedrine are both of value in certain cases of heart-block, but should not be employed without thorough investigation and consideration of each individual patient.

Effort Syndrome

Q—A patient with a history of several years' mental and emotional and sometimes physical strain presents the following picture: lack of mental ability, failure of memory, concentration, interest, lack of energy—extreme fatigue induced by slight physical or mental effort with palpitations. Routine physical examination reveals nothing abnormal. What are the diagnosis and treatment?

A—This appears to be a typical case of Da Costa's or "effort" syndrome, investigations concerning which were made in the 1914-18 war by Lewis, and at Mill Hill Hospital and elsewhere during the recent war. The conclusions seem to be that the condition is essentially psychological, or at least emotional. Reference should be made to contributions in this *Journal* (May 24, 31, and June 7 1941), and in the *Proceedings of the Royal Society of Medicine* (1941 34 541). Constitutional factors as in many psychosomatic disorders, may play at least some part. In any case the treatment is more difficult than that of other psychoneuroses, and apart from radical analytical treatment little can be done except by gradual rehabilitation.

Suspected Pituitary Deficiency

Q—A man of 29 developed normally until about 14 years of age since when growth has been arrested. His height is now 5 ft 3 in (160 cm); he is thin, pale, with little energy and has no facial axillary or pubic hair, the genitalia are infantile in type. He has a normal male voice and his intelligence is not affected. He has frequent erections but no nocturnal emissions. Recently after injections of testosterone he felt fitter and more energetic and his testicles doubled in size. He then took testosterone tablets with no effect and his testicles returned to their original size. He is distressed about his condition as he wishes to marry. Is this advisable?

A—There is insufficient evidence to make a definite diagnosis in this interesting case. A response to gonadotrophic hormone would have confirmed the clinical impression of primary pituitary deficiency. Radiography of the pituitary fossa might indicate a pituitary or parapituitary neoplasm. Examination of the fundi and visual fields might prove of interest. Deficient height at the age of 29 favours the clinical diagnosis of pituitary deficiency. It is worth trying gonadotrophic hormone but the effect both of this and of testosterone is likely to endure only while treatment is continued. Secondary sexual characteristics and potency but not fertility will be enhanced by testosterone. The enlargement of the testicles after testosterone is interesting, they usually remain the same size, as testosterone has no direct

action on them. Marriage is inadvisable unless the condition is fully explained to the contemplated bride and a responsible relative.

Effect of Amphetamine

Q—*Amphetamine taken before meals seems to reduce the appetite. This might be of benefit in obesity but would it predispose to gastric ulcer? Is the initial stimulation of the brain followed by depression? Any other pharmacological points would be welcomed.*

A—Amphetamine has been shown to reduce the appetite of rats. It affects the normal human stomach by first stimulating it so that emptying is hastened and later inhibiting its action so that emptying is delayed. There is increased pyloric tone, though in spastic states there may be the opposite effect—a relaxation of spasm. Gastric acidity is not appreciably affected by amphetamine. The stimulation of the brain produced by the drug leads to prolonged wakefulness at a time when the subject would normally be recruiting his strength by sleep; thus reserves are exhausted and collapse is common. While some can take the drug for long periods without collapse occurring others are adversely affected much earlier. Patients receiving amphetamine may complain of flatulence, anorexia, nausea, abdominal pains and an increase or a decrease in bowel movements.

Phenylmercuric Nitrate and Chloride

Q—*I would like information about phenylmercuric nitrate and phenylmercuric chloride. What are their possible therapeutic uses?*

A—Phenylmercuric nitrate and phenylmercuric chloride are powerful fungicides and germicides and when taken by mouth they exert a strong bacteriostatic and bactericidal effect in the blood, the cerebrospinal fluid, the bile, the urine, and the faeces. They have a low toxicity, for rabbits the minimum lethal dose of the nitrate is 0.01 g per kilo when given intravenously and 0.03 g per kilo by mouth. When 250 ml of 1 in 1,250 solution (0.2 g) was taken orally by a human subject the only effect was a rise of pulse rate by 20 though it caused a feeling of astringency in the mucous membrane of the mouth. These substances have no toxicity when applied to the skin, on which phenylmercuric nitrate is used in a strength of 1 in 3,000. This substance is stated to be 78 times as potent against Gram positive cocci as mercuric chloride. It is useful in ringworm and epidermophytosis (Levine, *J Amer med Ass* 1933, 2, 2108).

Insect Repellents

Q—*Can you recommend any new insect repellents for topical application for a patient residing in Calcutta who is particularly susceptible to insect bites and stings?*

A—Dimethyl or dibutyl phthalate rubbed on the skin gives satisfactory protection for several hours against most insect bites. These substances may cause smarting on abraded skin or in the eyes but are otherwise innocuous. They are solvents of many synthetic plastics and consequently contact with plastic watch-glasses, spectacle frames, etc. should be avoided. They may be used alone or incorporated into lotions or creams. They are not repellent but are lethal to mites, and rubbed into clothing are a most valuable protection against scrub typhus.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Assistantship Expenses

T started as an assistant in general practice on Jan 1, 1947, he asks what are the usual expenses which can be claimed.

****** A salary as an assistant is assessable under Schedule E, and the statutory rule is that only those expenses which are incurred wholly, exclusively and necessarily in the performance of the duties of the office can be deducted. The main allowable expense is the cost of maintaining and running a car. T can claim an initial allowance (20% of £295=£59) and wear and tear allowance (¼ of 25% of £295=£37) as deductions from his earnings for the quarter from Jan 1. Any other expenses which he is required by the terms of his engagement to bear can also be deducted—the cost of professional use of telephone. He should get in touch with the local tax office and obtain an adjustment of his present coding.

Letters and Notes

Sir William Macewen

Mr J MENZIES CAMPBELL (Glasgow) writes. I recently read a considerable pleasure and profit, Dr Harley Williams's book, *Doctors Differ*. Although no one can controvert the austere and autocratic manner of Sir William Macewen, nevertheless I feel that another aspect of his nature should not pass unnoticed. The following incident occurred in the year of Sir William's presidency of the British Medical Association. A friend of mine (an dentist in New York) was spending a golfing holiday at Turnberry. Unfortunately an abrasion in his hand became septic. He at once to Glasgow and telephoned that afternoon asking me to arrange an appointment for him with the best surgeon. I straightway telephoned Sir William Macewen who personally answered the call. I explained the circumstances, and no one could have been more sympathetic and co-operative. He mentioned that he was the moment overwhelmed with business relating to a B.M.A. meeting which he was to attend in London next day and for he was leaving within a few hours. He asked me to request a friend to take a taxi to his house and he would meet him. After leaving Sir William the American called to me of the great kindness which he had received. Sir William personally incised the finger and dressed and bandaged the wound. He met the inquiry about a fee with the response, 'There is no fee—we were pleased to be of any service to you.'

Half Cost, Double Value

Dr JOSIAH OLDFIELD (London W1) writes. Medical men are of great service at this particular juncture, when fuel is so scarce by teaching in every house they visit that in order to obtain a hot bath in perfection the ordinary bath should be covered in so as to turn it into a miniature Turkish bath. All that is needed is either to put a small clothes horse across the bath or even a frame of boards or battens, and to lay over this frame either an old blanket or rug or even a few sheets of brown paper. Space should be left at the head end to slip into the bath, and the quantity of water will give a more perfect bath by using the steam which lies above the water in place of filling the bath up to the usual full capacity.

Marriage Guidance

Dr PHILIP M BLOOM (London, W1) writes. The discussion of the House of Lords last week following the Denning Report is most interesting and certainly a most important peak in educational history. The proposals of the Government to welfare officers and to give material aid to the various clinics dealing with the divorce problem are most encouraging to those of us who are interested. I feel, however, that too much emphasis has been laid on solving and trying to adjust unhappy marriages rather than preventing them. I desire to put in a strong claim for more pre-marital guidance and instruction. The marriage guidance and some clinics deal, *inter alia* with this latter subject, but the importance of it has not been sufficiently stressed. A few young couples are already seeking help and my experience is that they are eager for information. I have no doubt that with encouragement many more young people would seek guidance. Pre-marital education and instruction along comprehensive lines go a long way towards preventing the development of incompatibilities and unhappiness in marriage.

Co-opted Members on Negotiating Committee: Correction

Dr D H STUART BOYD writes. The letter from myself (April 11, p 469) contains an error which I unfortunately overlooked when signing. The phrase "bestowed on the negotiation and election of the Negotiating Committee" should of course have been "bestowed on the nomination and election of the Negotiating Committee."

Correction

A typist's slip caused Dr A M Nussey's name to be in our report of the meeting of the Section of Endocrinology of the Royal Society of Medicine in the *Journal* of April 12 at p 491.

VITAMIN A IN INFECTIVE HEPATITIS

BY

A. D. HARRIS, M.R.C.S., L.R.C.P.

(Late House-Physician M.R.C. Jaundice Research Team)

AND

T. MOORE, D.Sc., Ph.D.

(Dunn Nutritional Laboratory University of Cambridge and Medical Research Council)

Addendum on Dark-Adaptation by the late K. J. W. Craik, M.A., Ph.D., and S. J. Macpherson, B.Sc. (M.R.C. Applied Psychology Unit), and A. D. Harris, M.R.C.S., L.R.C.P.

is the main storage place in the body for Liver diseases of various types may therefore do to interfere in one way or another with the and physiological activity of vitamin A various forms, reduced vitamin A levels in the blood plasma, and defective dark-adaptation been reported to result from deficiency of secondary to damage to the liver

The early literature on the occurrence of xerosis case has been reviewed fully by Altschule (1935) than 50 years ago, before the discovery of vitamin A, (1894) described the development of keratomalacia his old infant suffering from jaundice. Later Bloch ved xerosis and arrested growth in a jaundiced child on persisted even when cod-liver oil was administered up when bile appeared in the faeces

Levels—Chemical estimations of vitamin A were to subjects who had died of cirrhosis of the liver, investigators agreed that the vitamin A reserves were usually low and often undetectable (Wolff, and Scalabrino, 1934; Moore 1937). In acute cases, however, the hepatic reserves may not be although the level in the blood plasma is often low (Gmamn, and Zevin, 1943)

Adaptation—With defective dark-adaptation as a not workers have found that the vitamin A status is though opinions differ as to the value of vitamin in correcting this abnormality (Jeghers 1937, Haig, Patek 1938, Patek and Haig 1939, Ezickson, 1939, Feldman, 1940, 1941)

ent paper deals with abnormalities in vitamin A in infective hepatitis only. In preliminary (described below in an Addendum) defective tion was used as an indication of vitamin A. It was found that the mean final rod n patients tested soon after admission to hospital nificantly from the mean value for the same r recovery, and also from that of normal young r our main investigation, however, chemical re exclusively used. Vitamin A and carotenoids a were estimated in the early stages of the dis- ang convalescence. Parallel examinations were ne cases of the serum bilirubin, plasma prod- hippuric acid synthesis. Other patients were e doses of vitamin A, with a view to studying v of its absorption from the intestines and of

its transfer to the blood plasma. The vitamin A reserves of the liver were estimated in three fatal cases of hepatitis

Material and Methods

The main investigation was made on 32 military patients admitted to an E.M.S. hospital under the M.R.C. Jaundice Research Team. 30 suffered from infective hepatitis and two from arsenotherapy jaundice, which presents a similar biochemical picture. None had a history of transfusion. The ages ranged from 18 to 41 (average 25). The patients received a normal diet, without restriction of fat and without extra protein or vitamins. A few cases were included in a clinical trial with methionine, but this substance did not appear to be beneficial (Wilson, Pollock, and Harris, 1945) or to affect the vitamin A status.

The technique used to estimate vitamin A and carotene was essentially that of Kimble (1939), as modified by Yudkin (1941) and by ourselves. The plasma was shaken with alcohol and petrol ether. Carotenoids were estimated in the extract by their yellow colour. The extract was then evaporated and the vitamin A estimated by the blue colour produced on treatment with antimony trichloride, an allowance being made for the colour contributed by carotenoids to this reaction. Both yellow and blue colours were measured in a photoelectric absorptiometer provided with filters. In calibrating this instrument against vitamin A acetate a conversion factor of 1600 between $E_{1\%}^{1\text{cm}}$ at 328 m μ and i.u. of vitamin A per g was assumed. The calibration for carotenoids was against the International Standard solution of β carotene, and for convenience results have been expressed as though all the carotenoids of the plasma were β carotene. Because of the presence of xanthophyll, α carotene, etc., the actual biological value of the carotenoid fractions was presumably somewhat less than the figures given. Values for both vitamin A and carotene are expressed in terms of i.u. per 100 ml of plasma.

Serum bilirubin was estimated by the method of Mallory and Evelyn (1937). The prothrombin indices were determined by a method similar to that described by Harris (1943) using viper venom. Quick's (1939) modification of the hippuric acid synthesis test was employed, the results being expressed as grammes of sodium benzoate detoxicated in the first hour after administration.

Plasma Vitamin A and Carotene in Infective Hepatitis

Infection and Recovery—Observations of plasma vitamin A and carotene at various stages of the disease

ere made in 32 patients (Figs 1 and 2) and the mean values are shown in Table I, grouped in five-day periods from the date of admission. The earliest group (0-4 days after admission) show a mean value of 54.6 i.u. per 100 ml, which may be compared with a mean value of 118 i.u. for a group of 41 healthy adults (Leitner and Moore, 1946)

FIG 1—Plasma vitamin A in 32 cases of infective hepatitis

Successive estimations show a continuous rise until a mean value of 114.3 i.u. is reached for the group at 15-19 days after admission. Subsequently the observations are too few to be relied upon, and the readings from 20 to 29 days were combined, as were those for over 30 days from admission. There was, however, a suggestion in individual

TABLE I—Plasma Vitamin A and Carotene in 32 Cases of Infective Hepatitis

Days after Admission	Vitamin A			Carotene		
	No of Observations	Mean Plasma Vitamin A I U per 100 ml	Standard Error	No of Observations	Mean Plasma Carotene I U per 100 ml	Standard Error
0-4	27	54.6	± 3.7	27	67.2	± 6.1
5-9	10	64.8	± 6.0	10	51.3	± 9.0
10-14	9	80.4	± 12.0	10	78.9	± 10.3
15-19	10	114.3	± 13.2	10	84.8	± 7.4
20-29	12	124.3	± 11.9	11	118.2	± 17.3
Over 30	15	123.9	± 12.2	15	114.8	± 9.8

The number of observations for vitamin A and carotene does not tally in every age group because on two occasions a reading was obtained for one without a corresponding reading for the other.

patients that the plasma vitamin A may be unusually high during convalescence. This phenomenon has been noticed by Josephs (1943) in young children recovering from pneumonia. Plasma carotene values were also low in the early stages of the disease, the mean for the first period of five days being 67.2 i.u., as compared with 161 i.u. for healthy adults. During recovery the mean rose to 118.2 i.u. for 20-29 days after admission, but few cases reached the

normal mean even 30 days or more after admission. The correlation between corresponding readings for vitamin A and carotene was low ($r=0.2143$ for ungrouped data, $N=81$) and was barely significant.

Effect of Age, Fever, and Anorexia.—The effects of these factors were examined in 25 patients in whom blood

FIG 2—Plasma carotene in 32 cases of infective hepatitis

vitamin A had been estimated within four days of admission to hospital. If there was more than one such reading the earlier value was used. In Table II these readings are grouped according to the age of the patient, the highest temperature recorded, and the duration of anorexia, the significance of the results is also estimated. The duration

of anorexia did not appear to influence the plasma vitamin A. Higher mean values, however, were found for those under 25 years of age than for those over, and for those who showed no significant fever—under 99° F

(37.2° C)—than for those who did both these differences were shown by the *t* test to be significant. It cannot be excluded that the effect of age was due to greater severity of the disease in the older men and to a higher incidence of fever in the more severe cases, and not to a direct relation between age or fever and plasma vitamin A. In fever other investigations have shown that there is a direct lowering of the plasma vitamin A, since this action is found in artificial pyrexia as well as infectious fevers (Clausen and McCoord, 1938). In any case this mechanism can only be of subsidiary importance, since instances of abnormally low plasma levels were found in the younger age groups and in the group without fever.

Relation to Bilirubinaemia and Liver Function Tests—In nine cases in which serial estimations of plasma vitamin A were made, serial readings were also obtained of serum bilirubin, plasma prothrombin, and hippuric acid synthesis. The mean values for five-day groups are shown in Table III. No observations are available on the pre-

TABLE III—Relation of Plasma Vitamin A and Carotene to Serum Bilirubin, Prothrombin Index and Hippuric Acid Synthesis. 9 Cases with 4 or more Serial Observations of Vitamin A and Carotene

Over 30	6	147.0	6	126.0	13	1.11	4	98.0		

icteric stage of the disease, since the diagnosis of infective hepatitis is seldom made before the appearance of jaundice. However, most patients were admitted with a rising serum bilirubin, and the highest value was found in the 5-9-day group. It is notable that the plasma vitamin A was increasing from the time that the patients were first seen, and this improvement may be compared with the results of hippuric acid synthesis tests, which were also improving or stationary at a time when the serum bilirubin was still rising. Pollock (1945) has dealt with the improvement in hippuric acid synthesis in infective hepatitis and concludes that maximum liver damage in this disease occurs in the pre-icteric stage. In our investigation the parallelism between plasma vitamin A and hippuric acid synthesis was fairly close in individual cases. Curves for two illustrative cases are shown in Fig 3.

Relation to Prothrombin Index—Prothrombin values were low in the early stages of the disease, though spontaneous haemorrhages were not observed. During recovery the plasma prothrombin returned to normal in general parallelism with the plasma vitamin A. Examination of individual case records, however, revealed no close or regular relationship. The prothrombin values exhibited a wider day-to-day variation, and tended to return to normal at about the same time or later than the plasma vitamin A. Plasma was also examined from five patients not included in this series who persistently had very low prothrombin values. The plasma vitamin A in these cases was not unusually depressed, and when the prothrombin index rose in response to parenteral administration of vitamin K analogues there was no parallel alteration of the plasma vitamin A. In four of the five patients, however, a rise in plasma vitamin A occurred some time after the prothrombin index had returned to normal.

Absorption of Massive Doses of Vitamin A

Several workers (Breese and McCoord, 1940, Ralli, Bauman, and Roberts, 1941, Breese, Watkins, and McCoord, 1942, Spector, McKhann, and Meserve, 1943, Popper, Steigmann, and Zevin, 1943, Steigmann and Popper, 1944, Aldersberg and Sobotka, 1944) have measured the plasma vitamin A at intervals after giving massive doses of the vitamin*. In normal subjects the

plasma level increases rapidly after dosing to a maximum in about five hours, and usually subsides to the original value within 24 hours. We have confirmed the finding that in infective hepatitis the plasma vitamin A sometimes fails to respond to dosing although our results for a series of cases have been erratic. Thus in preliminary tests two patients in the early stages of the disease were given 96,000 i.u. of vitamin A in the form of four "prepalin" capsules. Subject C, whose resting plasma vitamin A of 84 i.u. per 100 ml was but little below the normal mean, had a value of 77 i.u. after dosing. Even after four further doses there was still no significant increase in the plasma vitamin A. In contrast patient D when first tested had a plasma vitamin A of only 50 i.u. Greater derangement of vitamin A metabolism than the

FIG 3—Relation of plasma vitamin A to serum bilirubin and hippuric acid synthesis. A: arsenotherapy jaundice. B: infective hepatitis. ● = Plasma vitamin A (i.u. per 100 ml). × = Serum bilirubin (mg % × 10). □ = Intravenous hippuric acid synthesis (g sodium benzoate detoxicated in 1st hour × 100).

* Experiments by this procedure are called 'tolerance tests' by some workers. The subject's resistance to toxic excess of vitamin A (Moore and Wang, 1945) is not, however, under consideration and mention of 'tolerance' is perhaps misleading. 'Absorption tests' seems a better description.

subject might therefore have been expected. Nevertheless, after dosing, the plasma vitamin A responded with a rise to 299 iu, which can be considered normal.

Reaction to Isolated Doses of Vitamin A—In further experiments (Table IV) five patients were given single doses of 96,000

penultimate dose had been given a period of 36 hours was allowed to elapse so that the plasma vitamin A might reach a resting level before giving the final dose. A specimen of blood was then taken again five hours after the last dose. It will be seen from Table V that in both cases the increase in the

TABLE V—Effect of the Frequent Massive Doses (96 000 I U) of Vitamin A on the Plasma Vitamin A

Case	Days after Admin	Plasma Vitamin A			
		No. of Doses Received	Before Dosing (I U)	After Dosing	Difference
M	1 32	1 31	80 227	108 473	28 246
N	1 32	1 31	70 150	68 406	—2 256

plasma vitamin A was much greater after the last dose than after the first. These results, taken in conjunction with those for subjects F and H (Table IV) agree with the conclusion of Breese and McCoord (1940) that in those subjects in which defective absorption is found in the early stages of the disease improved absorption may be expected during recovery.

The Liver Reserves of Vitamin A in Infective Hepatitis

There were no fatal cases in the present series, but necropsy material was obtained from other sources. Specimens of liver from two cases of acute yellow atrophy following infective hepatitis, or homologous serum jaundice, were kindly supplied by Capt J A R Miles, R A M C. Values of 225 and 500 iu per g were found. Another specimen was kindly supplied by Dr J F Gaskell, of Addenbrooke's Hospital, and in this instance the evidence showed that the low blood vitamin A in infective hepatitis is not necessarily associated with a depleted liver reserve. Although shortly before death the plasma vitamin A was only 19 iu per 100 ml, with carotene 68 iu, the liver contained 900 iu per g. None of the above patients had been specially dosed with vitamin A.

In a recent survey of the vitamin A reserves of the population of this country in cases of accidental death (Moore, T, unpublished data) a wide range of values was found, with a median of about 300 iu per g of liver. So far as can be judged from the small number of subjects, therefore, there is in acute liver disease no severe depletion of the pre-existing vitamin reserves such as commonly occurs, for example, in cirrhosis of the liver or in chronic nephritis, for which diseases median liver reserves of 6 and 25 iu per g respectively have been reported (Moore, 1937).

Discussion

Both acute febrile illnesses and diseases of the liver affect the metabolism of vitamin A. Since infective hepatitis presents a combination of these lesions the disturbances in vitamin A metabolism will obviously be complex. In the present investigation we have observed in the acute stage of the disease (1) reduced plasma vitamin A and carotene, (2) failure of the plasma vitamin A to respond to massive dosing with vitamin A, and (3) the excretion of large amounts of vitamin A in the faeces after massive dosing, with traces also in the urine.

In experiments at Sheffield with human volunteers the plasma vitamin A decreased only slightly after restriction for some months to a diet virtually devoid of carotene and vitamin A (Med Res Cncl Vitamin A Subcommittee, 1945). Levels of the order of 30 iu per 100 ml of plasma, at which defective dark adaptation was observed, occurred only in subjects deprived of the vitamin for over a year. Since in our experiments equally low values were often found in patients with infective hepatitis in the first few days of their illness, the brief initial period of anorexia clearly cannot in itself account for the decrease in plasma

iu of vitamin A at an early stage of the disease, and again on one or more occasions during the later stages. Estimations were made not only of plasma vitamin A but of the excretion of the vitamin in the urine, and in three cases in the faeces. For comparison the same procedure was followed in three normal subjects.

Plasma—In the normal subjects the smallest increase in the plasma vitamin A after dosing was 206 iu. In infective hepatitis the smallest increase was only 32 iu and the mean increase for all tests in the whole group was 148 iu. It is worthy of remark that no consistent difference in the extent of the response after dosing was found between the early and late stages of the disease.

Faeces—In normal subjects vitamin A is found in the faeces only after very heavy dosing. Even the massive doses given in the present experiments were not sufficient to cause faecal excretion of the vitamin in our control subjects. In contrast large quantities of vitamin A, amounting in one instance to more than half the dose given, were excreted in the early stages of the disease by all three patients with hepatitis whose faeces were examined. Even in the subject who excreted only 1,000 iu the presence of the vitamin was confirmed by the presence of an absorption band at 620 m μ in the SbCl₃ test. No vitamin A was found in the faeces of the same subjects during later stages of their illness.

Urine—After dosing, traces of vitamin A were present in the urine of two patients with hepatitis. Although the urinary loss was quantitatively insignificant it must be emphasized that in health the urine contains no vitamin A even after heavy dosing. Vitamin A is, however, excreted in the urine in certain diseases, and its appearance always has pathological significance (Lawrie, Moore, and Rajagopal, 1941).

An interesting abnormality was shown by subject H. For about a week after the first dose of vitamin A had been given the colour produced by the plasma extract with the SbCl₃ reagent was a faint orange in place of the usual blue. We were unable to ascertain whether vitamin A, or its oxidation products, played any part in producing this abnormal colour.

Frequent Dosing with Vitamin A—Two subjects were given massive doses of vitamin A frequently over a period of about four weeks. The total amount received was nearly 3,000,000 iu, which may be compared with the median total liver reserve of 500,000 iu (Moore, T, unpublished data). The course of dosing was therefore expected to alter the liver reserves substantially. The effect of the first dose on the plasma vitamin A was examined five hours after its administration. After the

vitamin A. Neither can a full explanation be found in the defective intestinal absorption of vitamin A and other fatty substances which is characteristic of hepatitis. In fatal cases the liver was found to contain adequate reserves of vitamin A, which in healthy subjects would have ensured a normal plasma level even if dietary supplies of the vitamin had been completely withdrawn. Failure in the mechanism for the release of vitamin A from the liver to the plasma must therefore be strongly suspected. One possibility, suggested by the recent experiments of Glover, Goodwin, and Morton (1946), is that there may be interference in the hydrolysis of vitamin A esters stored in the liver to liberate free vitamin A alcohol for mobilization into the blood stream. Any deficiency of the liver in this direction, however, may be intensified during fever by an increased expenditure of vitamin A in the plasma and tissues.

The position in regard to the carotenoid level is different. In the Sheffield experiment the plasma carotenoids, in contrast to vitamin A, fell to a low level soon after restriction to the deficient diet. The effect of anorexia in hepatitis cannot therefore be discounted. The stores of carotenoids from which the plasma may be replenished are, moreover, much smaller than those of vitamin A. The decrease in plasma carotenoids may be due to defective absorption and a decreased dietary intake, combined possibly with an increased rate of degradation during fever.

The complexity of the lesions in infective hepatitis, however, becomes most apparent when we consider the reaction to massive doses of vitamin A. We have seen that during the early stages of the disease the plasma vitamin A often fails to respond to dosing, and, moreover, that vitamin A is excreted in the faeces and sometimes in the urine. It might be expected that in individual cases these abnormalities would be interrelated and would all occur with about equal severity. Thus the loss of vitamin A in the faeces would at first sight afford a ready explanation of its failure to increase in the blood plasma. In our experiments, however, we have found no consistent correlation between the various disabilities involved in each case. For example when patient G was given his first massive dose of vitamin A about 40% was excreted in the faeces the plasma vitamin A, nevertheless, increased by 412 i.u. per 100 ml. In contrast when the same patient was later given a second dose there was no faecal excretion, but the plasma level was increased by only 89 i.u. In patient E abnormality in vitamin A metabolism was clearly indicated by urinary excretion, but after the first massive dose the plasma level increased by 279 i.u. We have already referred to the superiority of the response to massive dosing shown by patient D as compared with patient C, whose plasma had a higher resting level of vitamin A.

The most plausible explanation of these apparent anomalies is that the various mechanisms concerned with the metabolism of vitamin A are not always equally affected. Thus the absorption of vitamin A from the intestines, its deposition in the liver, its release from the liver to the plasma, and possibly its stability when present in the plasma may suffer to varying extents in different individuals. On the basis of this assumption patient C may have been unable to absorb vitamin A from his intestines but capable of mobilizing reserves from his liver into his blood stream. Patient G, on the evidence of faecal excretion in the early stage of his illness, could obviously absorb only part of his dose of vitamin A but possibly this abnormality was complicated by an even more severe disability in the liver's power to remove excess of vitamin from the blood stream. In that event the plasma vitamin A, denied its usual outlet, would "pile up" to a high level, and would thus convey a false impression of the efficiency of intestinal absorption.

The possibility of differences in the degree of impairment in the functions of the liver and the intestines, and of complications arising from pyrexia *per se*, must raise doubts as to the value of "vitamin A absorption tests" as a measure of the injury sustained by the liver. Repeated failure of the plasma vitamin A to respond to dosing even after pyrexia has subsided must strongly suggest damage to the liver, a good response to dosing, however, may not necessarily imply that liver function is normal. Moreover while we have found that the increase in plasma vitamin A during convalescence moves parallel with the improved values in prothrombin and liver function tests, and conversely to the plasma bilirubin, the interrelationships between these four criteria are not consistent enough to allow inferences as to the general condition of the patient to be drawn from estimation of the plasma vitamin A alone.

Summary

In the early stages of infective hepatitis the vitamin A content of the plasma was often very low. In estimations by the antimony trichloride method values of 30 i.u. per 100 ml or less were sometimes observed, as compared with an average of 118 i.u. previously found for normal subjects. The low plasma vitamin A seems an adequate cause of the impairment of dark-adaptation in this disease.

The age of the patient and the degree of pyrexia appeared to influence the extent of the fall in plasma vitamin A, but no correlation was found with the duration of anorexia.

During convalescence the plasma vitamin A increased until the mean for all cases equalled or exceeded the mean for normal subjects. There was no evidence that the vitamin A reserves of the liver were seriously reduced.

Variations in the carotenoid content of the plasma were similar to those found for vitamin A, but the return to normal was less rapid.

The changes in plasma vitamin A and carotenoids went roughly parallel with the prothrombin value and with hippuric acid tolerance, and moved in an opposite direction to the plasma bilirubin. There was perhaps a tendency for the recovery in vitamin A to begin slightly before bilirubin had started to decline.

In "absorption tests" with massive doses of vitamin A it was found that in the early stages of infective hepatitis substantial amounts of vitamin A were excreted in the faeces and sometimes there were traces in the urine. Excretion was not found in normal subjects given the same doses or in the same patients when dosed during convalescence.

In some cases the plasma vitamin A failed to show the usual rapid increase after massive dosing. No consistent correlation was found, however, between this defect and either faecal excretion of the vitamin or a low resting value in the plasma.

It appears that in infective hepatitis the mechanisms responsible for the absorption of vitamin A from the intestines for its deposition in the liver, and for its release into the blood stream are not always affected to the same degree. The interpretation of the results of "absorption tests" as a measure of the degree of injury to the liver therefore seems uncertain.

Our thanks are due to the M.R.C. Jaundice Research Team for allowing us to carry out investigations on their patients and in particular to Dr M. R. Pollock for liver function tests and to Capt J. A. R. Miles, R.A.M.C., for the prothrombin indices. We are also indebted to Dr L. J. Harris for his valuable criticism and to Miss A. C. Cooper for vitamin A estimations.

ADDENDUM ON DARK-ADAPTATION

In these experiments, which preceded and prompted the biochemical investigations described above, the course of dark-adaptation was determined by means of the Craik adaptometer in a group of 37 Service men with infective hepatitis. They were all tested within one week of admission, and serial tests were performed on a few patients throughout their stay in hospital, at intervals varying from a day to a week. An attempt was made to test all patients again one month after discharge, on their return visit from the convalescent depot, for administrative reasons this was possible in only 14 cases.

Apparatus and Method—A pea-lamp run at 2360 K illuminates a flashed opal screen subtending 7° at the subject's eye—at a distance of 2 ft 6 in (0.76 m)—through an opal window and a neutral wedge, which the subject moves by a long shaft. The position of the wedge is recorded automatically by a pencil on a rotating drum, plotting the logarithm of the threshold brightness against time. A celluloid disk with a 'V' can also be placed in front of the screen to test form perception, and a red fixation point of variable brightness is provided. Vision is binocular with natural pupils. The brightness range of the instrument is from 0.0000001 to 0.01 equivalent foot-candles. Tests are carried out in a dark room. The subject is first bright-adapted for five minutes by looking at a surface of 750 equivalent foot candles brightness. The light is then turned off, and he is instructed to turn to the adaptometer and to keep the test light just visible by moving the neutral wedge, looking in the general direction of the fixation spot but not staring rigidly at it, as this causes local fatigue of the retina. In this way a continuous record is obtained in the form in which such results are usually plotted—namely logarithm of threshold against linear time. Thresholds of light perception are expressed as the negative logarithms of the brightness in equivalent foot candles. A rise in the logarithm implies that a dimmer light can be perceived and that the efficiency of dark-adaptation has therefore increased. The final rod threshold is reached when the logarithm has reached a steady value consistent with maximum dark adaptation.

Defective Dark-Adaptation in Infective Hepatitis—The results of testing an unselected group of 37 patients with hepatitis and 20 normal men of comparable age are shown in Table VI. The final rod threshold was impaired in the hepatitis

TABLE VI—Final Rod Threshold in 37 Subjects With Infective Hepatitis and 20 Controls Mean Values

Days after Admission	No. of Observations	Final Rod Threshold
0-4	30	5.315
5-9	10	5.350
10-19	10	5.315
20-39	7	5.686
40-59	6	5.642
Over 60	5	5.710
Under 20	50	5.332
Over 20	18	5.678
Controls	20	5.758

patients, and no improvement in mean value was shown until 20 days after admission. The t test of significance was applied to the difference between the means in the following paired groups:

A Under 20 days from admission	5.332 log units
Over 20 days , ,	5.678 " "
B Under 20 days , ,	5.332 " "
Controls	5.758 " "
C Over 20 days from admission	5.678 " "
Controls	5.758 " "

The comparisons A and B showed significant differences ($t = 2.695$ with $n = 66$ and $t = 5.926$ with $n = 68$ respectively, both giving $P = 0.05$). In the comparison C the difference is insignificant ($t = 0.920$ with $n = 36$).

The Improvement in Dark-Adaptation during Convalescence—The same conclusion may be reached from Table VII, where

TABLE VII—Final Rod Threshold in 14 Subjects With Infective Hepatitis Retested in Convalescence

Case	First Test	Days after Admission	Second Test	Days after Admission
1	5.30	2	5.45	27
2	4.95	4	5.60	53
3	5.10	5	5.45	47
4	5.50	8	5.80	82
5	5.15	1	5.60	71
6	5.20	9	5.65	51
7	5.30	3	5.95	66
8	5.00	10	5.30	101
9	5.80	2	5.60	58
10	5.50	3	6.00	52
11	5.20	1	5.90	69
12	5.40	4	6.00	27
13	5.40	2	5.75	35
14	5.35	7	5.80	35
Mean	5.297		5.704	

the results for the 14 men who were retested during convalescence are shown independently. The mean values for final threshold were 5.297 during the active stage of the disease and 5.704 during convalescence, and again the difference is significant ($t = 4.892$ With 26 of freedom t need equal only 2.056 to give $P = 0.05$). The individual readings all improved except for one man whose threshold was initially within normal limits. An examination of the superimposed tracings of the curves provided by these 14 patients showed slight shortening of the rod-cone transition time with convalescence. Although the earlier curves lay within the normal range the shortening in transition time during convalescence occurred in 11 out of 14, which suggests that the earlier times were in fact abnormally long for these individuals. The range of the observed alterations was from 1 to 4½ minutes with a mean of 2½ minutes. No alteration in cone threshold was found.

Dosing with Vitamin A—Large doses of vitamin A (96,000 units) daily by mouth were given to four subjects, not included in the above tables, to see whether the final rod threshold could be restored to normal. The results shown in Table VIII are

TABLE VIII—Effects of Repeated Doses of Vitamin A (96,000 Units Daily) On Final Rod Threshold in Patients With Infective Hepatitis

Test Subjects				Controls		
Case	Days after Admission	Total Vitamin A Received	Final Rod Threshold	Case	Days after Admission	Final Rod Threshold
A	1	0	5.40	1	4	5.40
	2	96 000	5.70		13	5.60
	5	384 000	5.80		20	5.50
	8	672 000	5.90		27	6.00
B	1	0	5.20	2	2	5.40
	3	192 000	5.50		9	5.50

	9	768 000	5.60		23	5.85
C	1	0	5.10	3	36	5.75
	3	192 000	5.55		2	5.50
	5	384 000	5.75		11	5.35
	8	672 000	5.90		15	5.45
D	1	0	5.40		27	5.45
	2	96 000	5.60			
	5	384 000	5.95			
	8	672 000	6.00			

suggestive but not conclusive. Three patients returned to normal after eight days and the fourth improved considerably

This may be contrasted with the slow recovery in the other patients in the series and in the three controls shown in the table. There are two reasons, however, for caution in interpreting these results. (1) Final rod threshold is not a very satisfactory measurement to apply to small groups because of the range of individual variation, though it is believed that the differences shown here are too great to appear by chance. Again it cannot be excluded that as a result of the greater frequency of testing in these men facilitation of response may have contributed to the improvement. (2) The plasma vitamin A was estimated chemically in three subjects, and in two of them the rise produced by 96,000 units of vitamin A was so slight that it is difficult to see how it could have improved their dark adaptation.

Discussion

Vitamin A abnormality in infective hepatitis is associated with a rise of the final rod threshold and only slight alteration in the rod-cone transition time. This is the type of change that has been found in most experiments on simple acute dietary avitaminosis A. In contrast Haig, Hecht, and Patek (1938) found that in chronic liver disease the lengthening of the rod-cone transition time was as marked as the impairment of the final rod threshold. Similarly in the recent Sheffield experiments (Med Res Cncl, 1945) in which volunteers were kept on a vitamin-A-free diet for long periods the rod-cone transition time was affected as well as the final rod threshold. These differences may be explained by the suggestion made by Hecht and Mandelbaum (1939) that it may well be that this difference in behaviour of the rod-cone break is purely a matter of short-period avitaminosis versus prolonged deprivation.

It has previously been pointed out that dark-adaptation is less satisfactory as a measure of vitamin A abnormality than chemical estimation. In this trial, for instance, there was no diagnostic impairment in individual patients and statistical analysis was necessary to show the effect whereas using chemical estimation of the plasma vitamin A as an index a definitely abnormal result was obtained in most patients. The insensitivity in measurement of dark adaptation arises from two factors: the range of normal variation from individual to individual and the wide margin of error in the same individual found by repeated testing on the same day.

A second disadvantage is that dark-adaptation may be affected by other factors than vitamin A lack. Malingering can generally be detected with the Craik adaptometer, since a self-inconsistent record is produced but some psychoneurosis can cause poor dark adaptation (Wittkower, Rodger, Scott and Semeonoff, 1941). Pyrexia is a cause which can be disregarded in the present series, since most of the cases had no significant fever. It has been suggested that raised blood bile salts might play a part, as bile salt is a solvent for visual purple *in vitro*. No evidence was obtained for this when one of us (K J W C) after dark-adaptation was complete, was given an intravenous injection of bile salts. The injection was given by a dim light while the subject wore dark goggles and the record continued immediately. No alteration in threshold resulted either from bile salts or from the control injection of sterile water.

Summary

The course of dark-adaptation was investigated by means of the Craik adaptometer in patients with infective hepatitis.

The mean final rod threshold for 37 men tested within one week of admission to hospital was significantly impaired in comparison with that of 20 normal adults of comparable age.

In 14 men retested after an interval of one month or more the mean final rod threshold was significantly improved.

No alteration was apparent in cone threshold and the rod-cone transition time was only slightly prolonged.

Dark adaptation under the conditions of this experiment was a less sensitive measure of vitamin abnormality than chemical estimation of plasma vitamin A.

TUBERCULOUS PERICARDITIS

BY

HARRY KOPELMAN, M.D., M.R.C.P.

Pericardial effusion caused by tuberculosis has always been considered a rare condition, carrying with it a high mortality. Of recent years, however, more cases have been diagnosed as being due to tuberculosis, and doubt has been cast upon other cases which had previously been labelled rheumatic. Some of the many cases published have been proved to be tuberculous either during life or at necropsy, but in many a diagnosis has been presumed only by the presence of other tuberculous manifestations or by the absence of signs which have been taken to be rheumatic in origin. Thus in Harvey and Whitehill's (1937) collection of 95 cases taken from 45 years of records of the Johns Hopkins Hospital there are 37 proved cases, 34 unproved, and 24 proved in which the pericardial lesion was of no clinical importance. The mortality varied greatly in this series, in proved cases it was 83%, whereas in the unproved cases it was only 6%. There was little difference in the characteristic signs and symptoms in the unproved group from those in the proved group, and it was on these signs that the clinical diagnosis was achieved. These groups were further subdivided into those with large pericardial effusion and those without effusion, and while in the proved group of 37 cases 20 had effusion, in the unproved group 31 of the 34 cases had large effusions. In Ellman's (1945) excellent paper on this subject he quotes six cases, and, again, although the clinical picture and progress are strongly suggestive of tuberculous pericarditis, in three cases the diagnosis was not proved.

In all these series of cases in which the diagnosis has been tuberculous pericarditis with effusion the following features have been taken to be characteristic of the clinical picture: (1) no enlargement of the heart, (2) no gross murmurs or murmurs indicative of valvular involvement, (3) no rheumatic manifestation, and (4) no past or family history of rheumatism. In addition, there was no marked anaemia, an insidious onset, no leucocytosis, and, although the effusion might be large, the symptoms, especially precordial pain, were not marked.

Massie and Levine (1939) investigated 135 cases of rheumatic pericardial disease diagnosed by the presence of pericardial rub or pericardial effusion. They found that 110 cases had definite arthritis or arthralgia, one case had chorea, and 17 of the others had a past history of one or more attacks of rheumatic fever, sore throat, or a family history of rheumatism. On the other hand, of the 82 cases followed up for a period of seven years one-third had no evidence of any organic heart disease. Although Sheldon (1946) has recently published six cases demonstrating tuberculous arthralgia, acute rheumatism with serositis, and chronic rheumatism, this should not confuse the diagnosis with that of rheumatism if the criteria of the small heart, etc. are taken into consideration. While dealing with the differential diagnosis of tuberculous and rheumatic pericardial effusion it is also of interest to note that in Harvey and Whitehill's (1937) series several cases developed auricular fibrillation when the effusion was maximal, and that there was no evidence of myocardial involvement clinically or in those cases which came to post-mortem examination. In addition, these cases appeared particularly susceptible to digitalis, heart-block occurring with relatively small doses.

Pathology

Primary tuberculous pericarditis in the strictly pathological sense of the word is a very rare condition, and in the previously quoted series only one case at necropsy appeared to have the pericardium as the sole site of infection. On the other hand a pericardial effusion as a first clinical manifestation of active tuberculosis is not so uncommon. Although Blatt and Greengard (1928), after an extensive search of the literature, claimed their case of a child of 9 years as the youngest in which this condition had been diagnosed during life, one of the cases described below occurred in an infant of only 18 months.

Reisman (1901) described four means by which the pericardium might be affected: it may form part of a general miliary process, or part of a serous membrane tuberculosis, or be an extension from neighbouring structures, or, finally, develop independently. It seems generally agreed that the pericardial sac is relatively immune in a general miliary spread, and it appears that if miliary spread is present it is probably subsequent to the pericardial lesion. In most cases of tuberculous pericarditis involvement of the mediastinal glands has been demonstrated and it is probable that the pericardial lesion followed as a result of lymphatic spread. In one case described by Selgman and Lederer (1940) the pericardium was involved as a result of rupture of a caseous lymph node draining a Ghon lesion. This must, however, be as uncommon as pericardial involvement from the lung or the pleura.

Once the pericardium becomes infected the subsequent progress may follow the course taken by a case described by Barrett and Cole (1944). In this case there was increasing effusion with cardiac embarrassment lasting four months, followed by a phase of decreasing effusion with temporary recovery lasting three months, and, finally, increasing thickening and fibrosis of pericardium leading to congestive failure and death in three months. Although this may be the usual course in fatal cases, those that recover may have an effusion which is far more transient and which, with absorption of the fluid, gives rise to no residual signs or symptoms of pericardial involvement. It is in this type of case that the diagnosis is so difficult to prove, and most of the described cases have not been completely proved. In Barrett and Cole's case a guinea-pig inoculated with pericardial fluid lived from April 28 until Oct 8 (over five months) and appeared ill only a short time before death.

The age incidence of tuberculous pericarditis varies in the many cases reported. In Ellman's (1945) cases with effusion the ages ranged mainly between 20 and 35 years. In Heimann and Binder's (1940) 31 cases among Bantu patients the ages of those with large pericardial effusions ranged between 20 and 40 years. Another series, however, collected as primary tuberculosis of the pericardium, as judged by post-mortem examination, with the pericardium having the main or oldest tuberculous lesion (Thompson, 1933), the average age was 69.5 years (the range was 49 to 84) in the 28 cases described. These cases showed a pathological picture of adhesive caseous tuberculosis and a clinical picture of an insidious onset, cardiac enlargement, accompanied by a rapidly progressive and unexplained condition of cardiac insufficiency, together with pyrexia and wasting.

In the four cases described below only one is proved to be tuberculous, in two there is strong circumstantial evidence which makes the diagnosis probable, while in the fourth case there is a clinical picture which strongly suggests a tuberculous aetiology.

Case 1

A male child aged 18 months was admitted to hospital into an adult female ward on Aug 25 1945, with an impetiginous

rash over most of his body and two abscesses on his skull. Apart from a haemangioma the size of a shilling on the right side of the forehead nothing abnormal was found on clinical examination. The impetigo was treated with penicillin cream, the abscess was incised, and a penicillin sensitive haemolytic streptococcus was grown. Sulphamezathine—in all 11 g—was given. Under this treatment the condition soon subsided, and he became a great favourite in the ward. This unfortunate child, who had been in a very neglected and dirty condition on admission, was not wanted by his parents and with their consent, arrangements were made for his admission to a suitable home. As is usual in these affairs coupled with the fact that he had become a great favourite with the patients and the nursing and medical staff, the matter was not treated urgently and some weeks passed before the necessary arrangements were completed. By the first week of November 1945 some 11 weeks after admission, he began to get irritable, the temperature ranging between 99° and 100° F (37.2° and 37.8° C), with a pulse of 110–120. Finally, on Nov 10, 1945 his temperature rose to 104° F (40° C) and his pulse to 140–150.

On examination both drums were injected, especially the right, which showed some bulging, and myringotomy was performed. A course of sulphathiazole was started. Next day the patient looked much better, but subsequently he continued to run a swinging temperature of 100°–101° F (37.8°–38.3° C) and a tachycardia of 150–160, there was no evidence of bronchopneumonia, and his drum now showed a dry perforation. On Nov 15 his condition was unchanged, but during the day there was a steady rise in the respiration rate to 50 and examination showed an area of dullness over the front of the chest. The liver was enlarged and tender, and the tip of the spleen was palpable. The heart sounds were somewhat diminished in intensity. A radiograph of the chest confirmed the presence of a large pericardial effusion. Full doses of parenteral penicillin were started, it was thought that this was an infective condition secondary to that of his ears.

Pericardial paracentesis was performed under paraldehyde and local anaesthesia, the needle being inserted between the apex beat which was normal in position, and the outer border of the area of cardiac dullness. With some ease 130 ml of fluid were withdrawn and a little air replaced. The fluid was clear and pale amber green. Examination showed practically 100% small lymphocytes, no organisms were seen on direct smear and ordinary culture was negative. A guinea pig was inoculated with the fluid on Nov 20. After aspiration there was a dramatic improvement in his general condition, his pulse dropped to 120 and his respirations from 60 to 35. This was not maintained, there was a gradual deterioration in his condition and aspiration was repeated on Nov 22. This time 160 ml of fluid were removed and 10 000 units of penicillin instilled. There was little improvement after this and his condition remained unchanged except that both clinically and radiographically the effusion appeared to be getting smaller. Penicillin therapy was discontinued on Nov 26. His condition deteriorated further, and on Nov 30 pericardial aspiration was again attempted. This time it was obvious that the effusion was much smaller and that the pericardium was much more resistant to penetration, and it was only with difficulty that 60 ml of blood stained fluid were aspirated. In both these pericardial fluids no organisms were found and the cells were practically 100% lymphocytes. The white blood cell counts were as follows:

Date	White Cells	Polymorphs	Lymphocytes	Mononuclears
Nov 12	13 200	49%	40%	6%
21	22 400	41%	56%	3%
29	45 280	53%	38%	7%

The haemoglobin was 55%, the red cells numbered 4,940,000 per cmm and the colour index was 0.56. On Nov 24 the Mantoux test (1:100 000) was negative, and on Nov 29 it was doubtful positive (1:10 000).

The patient's condition remained unchanged, the pulse was still around 130 respirations 40, and temperature normal. By Dec 18 there was considerable oedema of the face and puffiness of the legs, which did not pit on pressure. There was also some distension of the abdomen. By Dec 23

this oedema had improved and a radiograph of the chest on Dec 27 showed a bilateral pleural effusion with a marked diminution in the pericardial effusion. His condition remained unchanged and oedema recurred. He became much worse on Jan 2, 1946, and died the next day.

Post-mortem examination showed a grossly thickened pericardium loosely adherent to a normal-sized heart. The pericardium was 1 cm thick and appeared fibrous. Sections showed tubercles in this tissue. There was an area the size of a shilling of a breaking down caseous lesion in the lingula of the left lung and caseation of the mediastinal glands immediately adjacent to the pericardium. There was a recent miliary spread in the lungs, liver, and spleen.

The guinea-pig was killed on Feb 5. It had appeared relatively well until this time, but there was evidence of tuberculous infection when it was examined post mortem.

Case 2

A soldier in the Royal Pioneer Corps aged 20 was admitted to hospital on March 6, 1945, complaining of breathlessness, pain in the chest, and cough. These symptoms gradually developed during the past four weeks while undergoing training in the Army. During the past two weeks he noticed that he was becoming increasingly breathless and that he had a pain below the right nipple which was worse at night and on coughing. He had also had a cough for some three weeks which was non-productive. He had no pain in any limb, but had an ache across the left shoulder for the last two or three days, which was worse on movement. There was no history of rheumatic disease.

On examination the temperature was normal, pulse 115, and respirations 25. He was sweating with no obvious joint involvement, and the left shoulder movements were full. *Cardio-vascular system*: Pulse was of poor volume, blood pressure 110/85. The apex beat was not palpable, it was 2 in (10 cm) from the midline in the fifth intercostal space. The area of cardiac dullness was greatly increased and extended to the right two fingerbreadths from the edge of the sternum and approximately 5 in (12.5 cm) from the midline, although the left border was difficult to determine owing to dullness on percussion at the base of the left lung. The heart sounds were very distant and best heard just within the nipple line, where they were accompanied by a soft systolic murmur. Pericardial friction rub was audible over most of the praecordium with maximum intensity around the left fourth costal cartilage. *Chest*: There was dullness to percussion below the sixth rib on both sides, with marked diminution of air entry; some rales were present. *Abdomen*: The liver was enlarged three fingerbreadths below the costal margin. The spleen was not palpable. There was no ascites or oedema. After resting in bed for some hours the pulse improved in volume and marked pulsus paradoxus became apparent.

Progress—The pulse became irregular and the pericardial rub disappeared but returned again on March 12. On March 14 the blood sedimentation rate was 27 mm in 1 hour, cell volume 45% corrected to 27 mm. The Mantoux reaction was negative 1:10,000. The patient continued to improve but had some dysuria and on March 25 the temperature rose to 102.8° F (39.3° C). A radiograph of the chest showed collapse of the left base as well as a large pericardial effusion. On April 6 the Mantoux reaction was positive 1:10,000. On April 20 pleural friction rub appeared in the right axilla and lasted five days. His condition remained unaltered; he still showed pulsus paradoxus and appeared very depressed mentally. During this time he had occasional pain in the chest but by May 23 this had disappeared and he was then feeling much better. On May 29 a radiograph of the chest showed the pericardial shadow to be much smaller and there was marked improvement in his pulse rate and general condition. The improvement continued until June 13 when he again did not feel so well; the pulse volume was poor and pulsus paradoxus recurred. A radiograph showed that the pericardial shadow was much larger. The blood pressure was 100/70. His condition continued unchanged until July 1 when there was obvious absorption of the pericardial effusion. He improved until July 25 when he was discharged to a convalescent home with only a very small pericardial effusion. He finally made a complete and uninterrupted recovery with no residual pericardial lesion.

Case 3

An unmarried woman aged 39 attended hospital on Aug 8, 1945, complaining of pain in the left shoulder and right chest for three weeks. There was no cough but some dyspnoea on exertion. She had had a hysterectomy in 1944 for fibroids. There was no history of pleurisy or rheumatic fever, and no family history of tuberculosis. Pain in the right lower chest had developed three weeks previously, it had been worse on deep breathing and had lasted about two days. It was replaced by aching pain in both shoulders diagnosed as fibrositis, and she was feeling out of sorts.

On examination the apex beat was 3½ in (8.75 cm) from the midline in the fifth intercostal space. There was impairment of the percussion note at the left base, with diminution of breath sounds. The heart sounds were normal and there were no murmurs but at the base to the left of the sternum a to-and-fro pericardial rub could be heard. The blood pressure was 120/80 and the pulse of good volume. The temperature on admission was 101° F (38.3° C), pulse 90, and respirations 20. A radiograph of the chest on Aug 8 showed an enlargement of the heart shadow on both sides. The liver and spleen were not palpable. There was no oedema.

Progress—Next day it became clinically obvious that the area of cardiac dullness had extended considerably beyond the apex beat, and a radiograph of the chest showed a large pericardial effusion with some pneumonic consolidation of the lingula of the left lung. For the next three days, until Aug 12, the pericardial effusion increased in size, the temperature remained around 101° F (38.3° C) and the pulse at 90 and she had pain over the praecordium. The area of cardiac dullness extended to the mid-axillary line and upwards to the second rib. The pulse was of poor volume, the apex beat was not palpable, and the heart sounds were diminished in intensity. A Mantoux test on Aug 10 was positive 1:1,000 old tuberculin. After Aug 13 the temperature settled to normal, the pulse to 72 and there was daily improvement in her general condition. It became clinically obvious that the area of cardiac dullness was rapidly diminishing, and by Aug 28 it was practically back to normal heart outline. A radiograph on Aug 22 showed the heart shadow to be normal in size, shape and position. The patient's general condition improved considerably, and a heart examination on Sept 7 showed the apex beat 3½ in (8.75 cm) from the midline in the fifth space, the sounds were clearly heard, and there were no murmurs. When last seen on Oct 12, 1945, in the out-patient department her pulse was 84 and regular, there was no enlargement of the heart, and no murmurs.

Subsequent Progress—She was readmitted to the County Hospital, Farnborough, in November, 1945, with left pleural effusion. Aspiration showed this to be typically straw-coloured tuberculous effusion, although no tubercle bacilli were actually seen in the fluid.

Case 4

A boy aged 11 was admitted on Nov 18, 1941, with pain in the epigastrium and right hypochondrium of two days' duration. This had been accompanied by vomiting and diarrhoea on the day of admission. During the previous five days there had been an unproductive cough accompanied by some mild headache, but he had been relatively well until the onset of abdominal pain. The previous medical history revealed nothing relevant.

On examination he looked pale and ill, his temperature was 102° F (38.9° C), pulse 120 and respirations 32. The heart sounds were muffled with dullness at both bases, especially the left, where there was marked diminution of air entry. The abdomen was tender in the right epigastrium and there was marked guarding of the right upper rectus. X-ray examination confirmed a diagnosis of a large pericardial effusion. On Nov 20 the heart sounds were more muffled, dullness extended from the right nipple to 1 in (2.5 cm) outside the normal left border of the heart and there was rigidity over the whole of the epigastrium.

Full doses of sodium salicylate were given with no effect. Sulphapyridine was substituted. An enema relieved the abdominal distension, and the liver was palpable three fingerbreadths below the costal margin. On Nov 24 a pleuro-pericardial rub developed and his white cell count was 12,000.

0 (54% polymorphs) After four days on sulphapyridine was no response and the temperature still ranged between 101° and 102.8° F (38.3° and 39.3° C). It was stopped after 3 g had been given. By Dec 4 the general condition was obviously better and there was decreasing cardiac dullness on the left, by the 12th the apex beat became palpable and showed no enlargement, the heart sounds were clearly audible, and there were no murmurs. There was still some tenderness of the liver, which was palpable, and a radiograph of the chest showed marked diminution in the size of the pericardial effusion. The patient was discharged to a convalescent home on Jan 17, 1942. In a radiograph of the chest taken before his discharge from the home the heart shadow appeared to be normal.

When seen subsequently as an out patient there was no enlargement of the heart, no murmurs, the sounds were clear and normal, and there was no tachycardia. There were, however, a fixed apex beat, dilated veins in the neck, and a palpable liver. Constrictive pericarditis was diagnosed. He was afterwards seen several times as an out patient, when it was apparent that the engorgement of the neck veins and the liver enlargement were becoming less, and on April 11, 1946, when he was admitted to hospital for dental extraction, there was no evidence of cardiac involvement, his pulse was regular, the apex beat was 3½ in (8.75 cm) from the midline in the fifth space, the sounds were normal and the blood pressure was 130/80. A radiograph of the chest showed a normal heart in shape and position, and no pulmonary lesion was seen.

This boy showed no rheumatic manifestations, no response to salicylates or sulphonamides, no cardiac enlargement, and no subsequent cardiac manifestations.

Discussion

Case 1 shows the development of a large pericardial effusion in a child of 18 months. The rapidity with which the pericardium contracted down and became thickened was very marked. This was almost certainly a primary infection, as the child had been in the ward for some weeks previously and during this time a case of open tuberculosis had been admitted for a short period. As has been noted by others the guinea-pig test may take several months to develop—five months in Barrett and Cole's (1944) case—and in some cases it may be negative and yet at necropsy or operation the aetiology be proved (Suzman, 1943; Sellors, 1946). In this case the guinea-pig survived for three months after inoculation. The patient had died before this.

In Case 2 the clinical picture is typical of this condition without rheumatic manifestations of cardiac involvement. The Mantoux reaction changed from negative to positive during the course of the illness. In Case 3 the subsequent development of a typical tuberculous pleural effusion makes it likely that this was the cause of the pericardial effusion. In this case there was great rapidity in the development and absorption of the effusion, the whole process taking little over two weeks. The fourth case shows no real evidence of a tuberculous aetiology, but there was marked absence of any rheumatic or cardiac manifestations and there was no response to salicylate treatment. Boas and Ellenburg (1940) claim that in rheumatic pericardial effusion salicylates in large doses produce a prompt relief in the general condition of the patient and a more rapid absorption of the effusion, although the actual endocardial involvement is not affected.

It is suggested that tuberculous pericardial effusion may be a commoner condition than previously diagnosed and that its prognosis is not nearly as bad as has been apparent. It may be argued that in many of the cases which have been quoted, including three of the four cases described, the actual causation has not been proved, and it is these improved cases which carry the best prognosis. This is similar to the position with regard to the so-called idio-

pathic pleural effusion in which the direct evidence of infection by the tubercle bacillus may be extremely difficult to prove, and yet follow-up of cases indicates that most of these are tuberculous in aetiology. The difficulty in proving an effusion to be tuberculous may further be stressed by the duration for which guinea-pigs survive. In Case 1 the guinea-pig survived long after the patient was dead, and in other cases (Suzman, 1943; Sellors, 1946) the guinea pig test was negative, although subsequently at necropsy or operation the lesion was shown to be tuberculous. Again, in Harvey and Whitehill's (1937) series of 13 proved cases in which paracentesis was performed five showed no evidence of tubercle bacillus by examination or guinea pig inoculation.

The analogy between pericardial and pleural effusion may be taken further: thus a large pericardial effusion may be a late primary tuberculous manifestation occurring in younger subjects secondary to mediastinal gland involvement. In these cases the tubercle bacilli would be scanty and difficult to demonstrate. The pericarditis may, however, progress to caseation and death, producing a condition similar to that which occurs in later life but terminates in an adhesive caseation. This would account for the higher age incidence in this latter type of case and for the higher mortality of those cases which prove easy to establish as tuberculous.

All cases of pericardial effusion without joint or other rheumatic manifestations should be considered as potentially tuberculous. Especially is this so when the heart itself remains small, though this may be difficult to determine with a large and radio-opaque effusion. In these cases paracentesis and air replacement is of great value in allowing the heart outline to be visualized. The value of pneumopericardium as a therapeutic measure in preventing pericardial adhesion and fibrosis is considered by some, however, to be slight. The fluid aspirated is usually similar to that of the pleural effusion, but may be blood-stained, the usual predominating cell being the lymphocyte. There are of course many other causes of pericardial effusion, and Smith and Willius (1932) in sorting 373 cases of pericarditis into adherent pericarditis, calcification of the pericardium, and pericarditis with effusion found that there were 113 in the latter group—77 were acute purulent and 30 were fibrinous, and only three were tuberculous and three of non-inflammatory origin. The fibrinous pericardial effusions were mainly secondary to intrathoracic infection, but even then nine of these cases might very well belong to the group now under discussion.

With regard to the development of Pick's disease it has been suggested that in the healing of such a pericardial effusion constrictive symptoms may develop and that as the process is one of healing there may be no pathological lesion resembling a tubercle left in the fibrous pericardium. Thus Norris (1911) collected 1,780 cases of tuberculosis of which 82 showed tuberculous pericarditis, but in only 32 were actual tubercles seen, while in the others no tubercles or any other demonstrable aetiology could be found. If this was so it would account for Smith and Willius finding tuberculosis present in only 2.1% of the 373 cases of Pick's disease examined.

Summary

Four cases are described. Only one case is bacteriologically proved tuberculous although the others strongly suggest a similar aetiology.

The proved case was that of an infant of 18 months in whom the pericardial effusion was the presenting clinical feature; the condition was diagnosed, although not proved, during life.

It is suggested that tuberculous pericardial effusion may be a commoner condition than has been previously recognized and

that it may be insidious in its onset, transient in its course, and complete in its resolution. It is also suggested that in some cases it may be a late primary tuberculous manifestation and analogous to pleural effusion.

The difficulty in proving the aetiology is stressed and the value of pneumopericardium in allowing the heart outline to be visualized is noted.

Guinea-pigs inoculated with pericardial fluid may survive for many months before showing signs of disease, and much longer than the conventional six weeks is required before passing judgment.

Gross pericardial thickening may develop in a relatively short space of time and this relationship with Pick's disease is considered.

All cases of pericardial effusion with a small heart and absence of rheumatic manifestations should be considered as potentially tuberculous unless proved otherwise.

I should like to express my thanks to the physicians of St. George's Hospital for permission to publish these cases and for their helpful advice.

MEDULLARY SUPRARENAL CHROMAFFINOMA PRODUCING MALIGNANT HYPERTENSION

BY

DAVID GUTMANN, MD

Assistant Physician Lister Emergency Hospital Huttlin Herts

The following case of medullary suprarenal chromaffinoma (phaeochromocytoma), with presenting features of intermittent attacks of paroxysmal hypertension and vasomotor crises, ending in malignant hypertension with uraemia as the cause of death, seems worthy of record.

Case History

A married woman aged 38 was admitted to hospital on Oct. 13, 1944. She complained of cough with sputum of several years duration and attacks of dyspnoea chiefly at night. These usually started with a feeling of discomfort in the lower abdomen followed by nausea and shivering, severe palpitation sensation of constriction in the chest, profuse perspiration, pain behind the eyes and marked tremor of the hands. The patient was kept under close observation and was examined during and between attacks which occurred about every third day. The following is a brief description of a typical one.

The attack was induced by the patient's turning on the right side whilst lying in bed. She became restless, trembled, was very excited and talkative and sweated so profusely that her underclothing was drenched with perspiration. There was pronounced tachypnoea and some dyspnoea and pallor, with cyanosis of the lips, ears, cheeks, hands and forearms. The forearms and legs were cold and white and the fingers and toes cyanotic. Pulsation of the brachial and radial arteries was palpable but in both dorsalis pedis and the popliteal and femoral arteries it was feeble. The pulse rate was rapid—approximately 130—but regular. The blood pressure was

300/170. The pupils were much dilated, the temperature was in the region of 100° F (37.8 C) and the urine contained albumin and sugar. Neck. The thyroid was not enlarged, there was no lymphadenitis, the trachea was central, there was no venous pulsation or engorgement. Chest. Signs of disease were absent save for a few scattered rales and rhonchi at both bases. Heart. This was slightly enlarged to the left. The cardiac impulse was forcible and diffuse and the sounds were normal. Abdomen. There was some fullness and marked tenderness below the right costal margin, but no rigidity in the right hypochondrium. Dullness to percussion was present over an area of about 2½ in (6.3 cm) in this region. The liver and spleen were not palpable. CNS. Some oedema was observed round the eyes, which watered profusely. The pupils were dilated but reacted promptly to light and accommodation. The retinæ showed bilateral papilloedema greater on the left side than on the right and multiple haemorrhages and discrete exudates. The reflexes were brisk. There were marked dermographism and tremor of the fingers, tongue, and upper lids. There were no other abnormalities.

The urine passed during an attack was copious, clear, and almost watery in colour, with a specific gravity varying between 1004 and 1010. It contained a slight trace of albumin and sugar (0.1 and 0.2%). The average duration of an attack was about half an hour.

After the attack the patient, though exhausted, was calm and placid, talking slowly and normally. The cyanosis and pallor soon disappeared, the skin became dry and the pulse slow (approximately 72) and the blood pressure fell below normal, varying between 90 and 100 systolic and 70 and 80 diastolic, only to rise slowly to about 200/120, which was her usual blood pressure between attacks. It remained fairly constant at that level until a further attack occurred, when it abruptly rose again to 300/170.

From the history and from physical examination during and after attacks a preliminary diagnosis of medullary suprarenal chromaffinoma was made. That it was on the right side was suggested by the fullness present below the right costal margin and by the fact that the attacks were precipitated by turning on to that side. There were no symptoms or signs indicating involvement of the cortex in the way either of hyperfunction resulting in "adreno-cortical syndrome" or of hypofunction resulting in Addison's syndrome.

Ancillary investigations were carried out with the following results.

A catheter specimen of urine after an attack showed specific gravity, 1008, albumin, slight trace, sugar, 0.2%, deposit occasional leucocytes, epithelial cells, a fair number of erythrocytes, hyaline and cellular casts, culture, sterile. Blood urea was 54 mg per 100 ml. From a urea-clearance test the renal function appeared to be 34% of the average normal maximum clearance and 24% of the average standard clearance. The glucose-tolerance test showed diminished tolerance as the fasting blood sugar was 150 mg per 100 ml 3¼ hr after 50 g of glucose, 270 mg, and in another 3¼ hour 260 mg. Lumbar puncture revealed cerebrospinal fluid under normal pressure. This was clear and colourless and contained 1 lymphocyte per cmm, protein, 30 mg per 100 ml, sugar, 130 mg per 100 ml, and chlorides 740 mg per 100 ml. The Queckenstedt test was positive.

Radiological examination of the skull showed no evidence of abnormality. The pituitary fossa was rather small but the clinoid processes appeared normal. Radiographs of the chest revealed some fibrosis in both lungs probably due to old healed tuberculous infiltration. Bronchial thickening was present at both bases.

X-ray examination showed that the heart was globular in shape suggestive of concentric hypertrophy of heart muscle without dilatation. An electrocardiogram revealed depression of S-T intervals in all leads, but otherwise it was within normal limits. Intravenous pyelograms showed that the kidneys were normal in size and position. Both excreted well. There was no evidence of any organic lesion in the urinary tract. No suprarenal calcification was found but there was a depression in one calyx of the right kidney probably due to external pressure and suggesting that the tumour was on the right side.

erythrocyte sedimentation rate was 59 mm in 1 hour (estergren). The white cells numbered 12,700, with a normal differential count. The Wassermann and Kahn reactions were negative.

As these clinical investigations strengthened the diagnosis of a right suprarenal chromaffinoma, it was decided to perform an exploratory laparotomy. Before this could be done however the patient had another severe attack which proved fatal.

Post-mortem examination—This was carried out at Charing Cross Hospital on Dec 5, 1944 and the report by Dr Vines was as follows: 'Brain No abnormality was found. The pituitary appeared normal. Thorax Lungs Both lungs showed some emphysema and chronic bronchitis, they were closely bound to the thoracic wall by chronic fibrous adhesions. In both lungs there was extensive patchy fibrosis at the apices, but no active tuberculosis was seen. Heart There was gross hypertrophy of the left ventricular wall. The tone of the muscle was good. The aorta was rather small and some early atheroma was present. Abdomen The only pronounced changes were seen in the kidneys and the right adrenal. In the latter there was a spherical tumour about 1 in (2.5 cm) in diameter projecting forwards. It felt soft and almost cystic, and was not incised. It did not appear to infiltrate, and no metastatic deposits were found. In both kidneys the cortical band was reduced in width and the capsules were adherent, leaving a finely granular surface. In the lower two-thirds of the right kidney there were numerous areas of cortical necrosis suggestive of malignant hypertensive changes, the total changes in the kidneys suggested uraemia as the ultimate cause of death.'

Histological examination of the adrenal tumour revealed a fairly typical medullary chromaffinoma. In accordance with the clinical evidence and the presence of an actively secreting tumour, the kidneys histologically showed well marked hypertensive changes with arteriosclerosis and necrosis. Although the adrenal tumour should have been easily removable, in view of the extensive renal damage it is unlikely that the patient would have survived operation.

There are, of course, reasonable grounds for belief that the accessory chromaphil bodies also secrete adrenaline. It is not surprising, therefore, that similar tumour masses should be found associated with one or other of these bodies anywhere in the sympathetic autonomous nervous system, causing similar paroxysmal attacks of hypertension. For instance, cases of paroxysmal hypertension associated with tumours of the carotid sinus and carotid body and also of the aortic bodies have been reported. The structure and function of both are probably identical. They consist of masses of glandular-looking cells arranged in characteristic clumps resembling those of chromaphil cells. Such a tumour of the carotid sinus or carotid bodies has often been mistaken for an enlarged cervical gland.

In essential hypertension cerebral hypertensive crises may simulate paroxysmal hypertensive attacks such as I have described. It is important to remember these occurrences in order that errors of diagnosis, and thus of treatment may be avoided.

Summary and Conclusions

A case of medullary chromaffinoma of the right adrenal medulla in a woman aged 38, diagnosed during life, is reported and the syndrome discussed. The patient unfortunately died from secondary malignant hypertension and uraemia before operation could be performed. The history of the case and the results of various examinations conducted during and after attacks are described.

The symptom complex was caused by a tumour of the right adrenal medulla which consisted of adrenalinic secreting chromaffin cells discharging into the blood paroxysmally though possibly also constantly small quantities of adrenaline. This caused hypertension with periodic exacerbations to very high levels—sometimes to over 300 mm Hg—glycosuria and when the kidneys became ischaemic, albuminuria and uraemia. The vasomotor crises were also due to a discharge of adrenaline into the blood stream.

The treatment is removal of the tumour, but this is likely to be successful only if it is recognized early and before permanent changes in the kidneys have occurred. The tumour, as in the present case, is seldom malignant and is usually unilateral. It can therefore be concluded that a certain proportion of all cases of paroxysmal hypertension are due to a hyperfunctioning medullary tumour. In this case there was evidently gross hyperfunction, but cases also occur in which the tumour is less active and the symptoms correspondingly less pronounced.

Within the past few years a number of tumours of chromaphil tissue have been reported some authenticated at necropsy, others actually removed surgically with beneficial results.

I have to thank Dr P J W Mills, medical superintendent, Lister Emergency Hospital Hitchin, for permission to publish this case, Dr H W C Vines for the post mortem and histological findings, Dr J W Linnell and Dr A A Cunningham for their kind encouragement and Dr C Hilliard and Dr M Brown and their technical staffs for the radiological and pathological investigations respectively.

A CASE OF PHAECHROMOCYTOMA

BY

J. M. K. SPALDING, B.M., B.Ch.

The surgical removal of a chromaffin tumour or phaeochromocytoma of the adrenal medulla is rare enough to warrant the report of a recent case.

Case History

The patient, a 24-year-old secretary, was admitted on June 4 1945, under the care of Prof Ellis, complaining of blurring of vision and of attacks of upper abdominal pain and vomiting with palpitations and headache. There was nothing relevant in her past history. The attacks began two years before admission and at first recurred about once every four weeks. They became gradually more frequent, and on admission she was having one or more daily. Immediately before an attack she had a premonition that it was about to occur. She then felt a burning pain in the epigastrium, followed by severe headache, nausea and often vomiting. She had severe palpitations, 'as though her heart would burst through her ribs,' her hands and face became pale, and she felt cramp like pains in the limbs. The attacks occurred at any time of the day or night and usually lasted 10 to 20 minutes, but might last an hour. On three occasions she had lost consciousness. After an attack she felt weak, her arms and face were flushed, and she had a sensation of pins and needles in her arms. Five months before admission she was examined elsewhere and found to have a raised blood pressure. The fundi and urine were normal but the cerebrospinal fluid contained 80 mg of protein per 100 ml. No record of the pressure of the cerebrospinal fluid at this time was available. She was noted as unduly excitable and her condition was dismissed as functional, a

diagnosis for which there was ample foundation in her social history. Four weeks before admission she first noticed blurring of vision in the right eye immediately after an attack, and two weeks later the left eye was similarly affected.

On examination she was "nervous" and anxious to demonstrate that her disease was not functional. There were no abnormal findings apart from the blood pressure, fundi, and urine, and there was no demonstrable enlargement of the heart or peripheral arteries. Blood pressure readings between attacks ranged from 120/80 to 250/170, and during attacks from 230/135 to 300+/205 mm Hg. Prof. Mann reported on the fundi:

The ophthalmic condition resembled that seen in albuminuric retinitis in that there were numerous flame-shaped haemorrhages, fluffy patches of exudate, and a well-marked macula fan, with slight blurring of the disk but no true papilloedema. The condition was not absolutely typical in that the arteries which were all reduced to threads, were narrower than is normal in albuminuria. The urine consistently contained a trace of protein, and its specific gravity varied from 1008 to 1024.

She had frequent attacks after admission and a moderately severe one was followed in detail. It began while the patient was sitting quietly in a chair. When seen three minutes later she looked pale and her respirations were deep and rapid. The cardiac impulse was extremely forcible, but the radial pulse was barely perceptible. There was marked 'goose skin', and the pupils were widely dilated and did not react to light. The blood pressure was 300/200 mm Hg, and the pulse rate 120. Ten minutes after the onset there was subjective improvement, after 15 minutes the systolic and diastolic pressure began to fall, after 30 minutes she became flushed and after one hour the blood pressure reached a resting level. It was another hour before the pupils returned to normal.

Special Investigations—The haemoglobin was 118%, the leucocytic count 7,000 per c mm, and the Wassermann reaction negative. The blood sugar during an attack was 107 mg, during an interval 120 mg per 100 ml. Ventriculography and examination of the cerebrospinal fluid revealed nothing abnormal. The patient was profoundly collapsed for 12 hours after ventriculography. An electrocardiograph showed left axis deviation and an inverted T₁ wave. Intravenous pyelography was normal. The right kidney was 4.5 cm lower than the left. A barium meal revealed no abnormality. An unsuccessful attempt was made to demonstrate the presence of adrenaline in blood taken during an attack.

A provisional diagnosis of phaeochromocytoma was made, and it was decided to explore the suprarenals. In answer to direct questioning the patient admitted having slight pain in the right loin, and she believed that lying on the right side precipitated an attack, it therefore was decided to explore the right side first.

Operation—This was performed by Mr. Corry on July 24 under ethyl chloride and ether anaesthesia. A tumour weighing 86 g was removed from the suprarenal region through an incision in the right flank. Neither induction of anaesthesia nor handling the tumour altered the blood pressure which remained about 180/150 mm Hg throughout the operation. But half an hour after the removal of the tumour the blood pressure fell to 80/60 and the patient appeared profoundly shocked. During the next two hours she was given 20 ml of 'eschatin' 20 minims (12 ml) of adrenaline and 1 pint (568 ml) of normal saline parenterally. At the end of this time the systolic blood pressure had risen to 100 mm Hg and her condition began to improve. During the first 24 hours after operation she was given 120 ml of 'eschatin'. Convalescence was uneventful and until she was discharged from hospital 18 days after operation her blood pressure maintained a steady level of 140/100. The lesions in her fundi were regressing when she left hospital and her eyesight was improving rapidly.

Fifteen months after operation she was doing a full-time clerical job with no symptoms and was about to be married. Her blood pressure was 135/100 and the urine was clear. Her vision was 6/5 on the right and 6/9 on the left, and was not improved by correction. Prof. Mann reported:

The disks are normal and the veins and arteries are of normal calibre and have healthy walls. The whole fundus colour is slightly pale. The macula however shows gross abnormality in both eyes being pigmented and covered with

small dots of exudate and minute atrophic patches all rather resembling senile macular degeneration. It is remarkable that with so definite an ophthalmoscopic change the visual acuity should be so good."

Pathology and Histology (Dr. Biggs)—The specimen consisted of an enlarged adrenal gland measuring 7.5 by 7.5 by 5 cm and weighing 85 g. Externally there was a thin layer of cortical tissue with a ridge of cortex over the upper pole. On section the medullary tissue was replaced by a homogeneous grey-white tumour. Microscopically the tumour consisted of dense masses of darkly staining cells separated by sinusoidal blood channels. The tumour nuclei varied in size, but there were few nuclear divisions and no giant-cell forms. The cells stored neither fat nor glycogen, but chrome fixation showed that the cells had an affinity for chrome salts. The general structure and histochemical reactions are characteristic of a phaeochromocytoma of the adrenal medulla, the regular pattern, the infrequency of nuclear divisions, and the absence of giant cells suggest that the tumour is benign. Biological assay, kindly performed by Prof. Burn, showed that it contained 5 mg of adrenaline per gramme of tumour (normal=0.4 mg/g).

Comment

The characteristic syndrome associated with phaeochromocytoma is paroxysmal hypertension with palpitations, headache, nausea, and abdominal pain (Padis, 1945). Pallor and tingling of the extremities are also common, profuse sweating sometimes occurs (Biskind *et al.* 1941; McCullagh and Engel, 1942; Evans and Stewart, 1942; Thorn *et al.*, 1944), and occasionally there is persistent hypertension (McCullagh and Engel, 1942; Thorn *et al.*, 1944). The adrenaline content of the tumour is variable, as much as 20 mg per gramme having been reported (MacKeith, 1944). Raised blood-sugar levels and glycosuria have been found in several cases (Duncan *et al.*, 1944). Post-operative shock is greater than would be expected from the severity of the operation and responds to large doses of adrenaline (Biskind *et al.*, 1941; Duncan *et al.*, 1944), and parenteral fluid has also been recommended (McCullagh and Engel, 1942).

Biskind and his colleagues (1941) reviewed 29 reported cases treated by operation. Five patients died soon after operation, 22 remained well for a period of 7 months to 13 years, 1 had a recurrence after 6 years, and 1 died from metastases. MacKeith (1944) collected 165 case reports, mainly from necropsies. In 16 of these the tumour was bilateral and in 15 malignant.

I wish to thank Prof. Ellis and Dr. Alice Stewart for their help in preparing this report, Prof. Burn and Miss Bulbring for biological assay of the tumour, and Prof. Mann for reports on the eyes.

¹ The L.C.C. has agreed, at the request of the Ministry of Health, to the establishment at Sutton Emergency Hospital of an industrial neurosis unit of 100 beds (50 for each sex). This will be used for the reception of persons apparently suffering from neurotic disorder and referred from employment exchanges. They will be given a trial, as in patients in industrial processes with a view to later treatment, training or employment according to their ascertained need. The whole hospital (500 beds), which has hitherto accommodated a number of general cases, is to be reserved for patients suffering from psychoneurosis, and will continue to rank as an emergency medical service hospital. Two full-time psychologists are to be appointed one for the industrial neurosis unit and the other for the remaining 400 patients.

SEMINAL FLUID ACID PHOSPHATASE
IN STERILITY

BY

G E DELORY, M Sc, Ph D

Biochemist Royal Infirmary, Preston Lancs

The discovery of large amounts of "acid" phosphatase in the seminal fluid and the prostate gland has proved of great value in the diagnosis and treatment of prostatic cancer. Nevertheless the fascinating question of the function of this enzyme still awaits an answer. The most obvious starting hypothesis is that the enzyme is concerned with spermatozoal motility, and it may be noted in this connexion that acid phosphatase is not present in the prostate before puberty, although it appears precociously in the rhesus monkey after injection of testosterone propionate (Gutman, Sproul, and Gutman, 1936).

It seemed worth while to estimate the acid phosphatase content of the semen of patients attending hospital for advice because of the sterility of their marriages, and to correlate the findings with observations of pH, volume, abundance, motility, and morphology of spermatozoa. If the enzyme played a fundamental part in maintaining optimal conditions for fertility, then we would expect to find a correlation between the enzyme content and the physical observations. At the same time a low enzyme content might have been demonstrated in samples of seminal fluid from patients who showed no other abnormality to account for their sterility.

Examination of the Seminal Fluid

The patients were requested to deliver the samples to the department as soon as possible after the emission. In the majority of cases the ejaculate was received into a condom and transferred immediately to a dry phial. Through the kind co-operation of Dr G B Manning and Dr C V Harrison samples were received from the Royal Infirmary, Bolton, and the Pathological Department of Liverpool University, respectively. In these instances the determinations of constituents other than acid phosphatase were carried out in the laboratories of the senders. Preliminary experiments showed that there was no serious diminution in enzyme content when the sample was analysed up to 48 hours after collection. No preservative was needed.

Each sample of seminal fluid was suitably diluted (usually 1 in 4,000) and the acid phosphatase content estimated as previously described (Watkinson, Delory, King, and Haddow, 1944). The other properties—pH, abundance, morphology, and motility of spermatozoa—were studied in the usual manner (Lane-Roberts, Shaiman, Walker, and Wiesner, 1939). The findings are given in the accompanying table. The correlation coefficients between the acid phosphatase content and the motility and between the enzyme content and the abundance of spermatozoa were 0.046 and 0.047, respectively, showing complete absence of correlation.

Discussion

From the table of results it will be seen that, although the lowest acid phosphatase figure recorded (244 units per ml) is from a sample showing no motility, the highest figure (7,000 units per ml) is also found in the presence of reduced motility. While the former figure is low, it still represents a considerable amount of enzyme, and it is difficult to believe that this would be insufficient to allow carbohydrate metabolism to proceed at the rate required to maintain an optimum degree of spermatozoal motility, if this indeed is the function of that enzyme.

Gutman and Gutman (1941) estimated the acid phosphatase content of samples from 24 sterile males. The semen contained only 33 units of acid phosphatase in one case, but all the others gave results within normal limits. They do not, however, report the results of any other examinations on the samples. There is no correlation in the present determinations between the acid phosphatase content of the seminal fluid and either the motility or the abundance of spermatozoa. This does not support the hypothesis advanced by Gutman and Gutman (1941) that the enzyme is responsible for spermatozoal motility. Mann

(1946) studied the reducing sugar of seminal fluid and found it to be *D*-fructose, he suggested that its main function was to supply the spermatozoa with readily glycolysable material.

Working with prostatic secretion obtained by digital massage, Lundquist (1946) obtained evidence leading to the conclusion that the function of acid phosphatase was the splitting of phosphorylcholine into choline and inorganic phosphate. On the other hand, Lardy and Philips (1941) have shown that when seminal fluid is stored there is an increase in the ester phosphorus at the expense of lipid phosphorus, and suggested that the fatty acid produced is then oxidized to provide energy for spermatozoal motility. In view of this work, samples of seminal fluid were tested for lecithinase by the method of King and Dolan (1933), but the presence of such an enzyme could not be demonstrated.

Since the metabolism of human spermatozoa is almost entirely glycolytic (MacLeod, 1939) it seems probable that acid phosphatase is not concerned with spermatozoal motility and that its function is still unknown.

Summary

Samples of seminal fluid from 36 men attending hospital for investigation of sterility have been examined for acid phosphatase content, pH, morphology, motility, and abundance of spermatozoa.

No correlation exists between the enzyme concentration and either the number of spermatozoa present or their motility.

There is no evidence that the acid phosphatase is constantly low in male sterility.

Lecithinase was not detected in the seminal fluid.

It is probable that acid phosphatase is not responsible for the maintenance of spermatozoal motility

Thanks are due to Dr G O Stephens for his help with the statistical analysis to Prof E J King for his valuable advice, and to Dr F B Smith for his helpful co-operation. The work on which this paper was based formed part of a thesis approved for the degree of Ph D in the University of London

Medical Memoranda

A Case of Sulphaguanidine Anuria

During the last few years sulphaguanidine has been extensively used to combat bacillary dysentery. The toxic effects of this drug have been very slight compared with the other members of the sulphonamide group though huge doses are sometimes administered. In view of the rarity of sulphaguanidine anuria the following case is presented

CASE REPORT

On Jan 10, 1946 an R A F corporal aged 32 was admitted to a British military hospital. For five days he had had abdominal pain and severe diarrhoea his stools containing blood and mucus. He was put on sulphaguanidine, 6 g immediately and 4 g four hourly. Before starting treatment however, two stools were sent to the clinical laboratory (these proved to be negative for pathogenic organisms). He vomited three times on Jan 13, and again early next morning. On the 14th he confessed that he had not passed urine for 24 hours and that he had not taken the prescribed amount of fluid.

On examination he was slightly anaemic and the bladder seemed empty. He was catheterized 9 oz (255 ml) of blood stained urine being withdrawn. The clinical laboratory reported heavy crystalluria in this specimen. His red blood cell count was 4,000,000 per cmm, haemoglobin 77% (Sahli) and blood urea 210 mg per 100 ml. Cystoscopy was performed. The catheter was passed up the left ureter to the limit, and 20 ml of 2% sodium bicarbonate solution was injected into the pelvis of the kidney. On withdrawal of the catheter good effluxes of blood stained urine were seen. The catheter would not go beyond 2 cm up the right ureter, and 40 ml of the bicarbonate solution was injected but on withdrawal there was no efflux into the bladder. The post-operative treatment consisted of fluids by mouth 20 ml of 40% sucrose intravenously, sodium citrate, and an intravenous drip of normal saline.

On Jan 15 he had occasional bouts of vomiting. The drip was changed to glucose. At 5.30 p.m. 4 oz (114 ml) of very heavily blood stained urine was withdrawn from the bladder. The intravenous drip had been continued all day the solution having been changed to 3.5% sodium sulphate. Next day his condition was unchanged and cystoscopy was again carried out. Peristalsis was seen down both ureters but there was no efflux from either orifice. The catheter in the left ureter was blocked at 5 cm from the orifice but on withdrawal an ordinary efflux was seen. Catheterization of the right ureter was unsuccessful. A second attempt to catheterize the left ureter was successful and the catheter was left in situ.

On Jan 17 his general condition was satisfactory and heavily blood stained urine was recovered from the indwelling catheter. The haemoglobin was 55% (Sahli). On the 18th he had an epistaxis and a slight haematemesis. While the catheter was left in position he was washed out with 5 ml of 1% sodium bicarbonate solution were given and up to 10 a.m. on the 18th 1.5 ml had been injected up the catheter and a total of 260 ml of blood stained urine recovered. Between 10 a.m. and 8 p.m. on the 18th the injection of fluid up the indwelling catheter was discontinued and during this time 105 ml of blood stained urine flowed down. At 11 p.m. an

ordinary rubber catheter was passed into the bladder and 24 oz (680 ml) of blood stained urine was withdrawn. There was no change in his condition on Jan 19. Next day the left ureteric catheter was withdrawn, but the bladder catheter was left *in situ*. Drainage was now satisfactory and the clinical condition slowly improved. The urinary output became normal, and iron was given to combat the anaemia. On Feb 5 the erythrocyte count was 3,030,000 haemoglobin 65% (Sahli). The patient's appetite was good, and he was very contented. On Feb 20 the blood urea was 30 mg per 100 ml, the red cells numbered 3,730,000, and the haemoglobin was 82% (Sahli).

COMMENT

Cystoscopy followed by ureteral catheterization is a life saving measure in these cases. It is suggested that the ureteral catheters be left *in situ* and that the kidneys be washed out with 1-2% solution of sodium bicarbonate the amount of fluid injected and the amount of urine subsequently collected being charted so that the return of kidney function may be assessed. Sodium sulphate 3.5% solution or glucose-saline should be given continuously by the intravenous route.

I wish to thank Lieut-Cols W D Hughes, R A M C and J Mackay Dick, R A M C for their kind advice and especially Major B Brookes, R A M C who carried out the surgical treatment. I should also like to thank Col R H C Pryn for permission to publish this report.

Empyema of the Gall-bladder in a Child

The following case seems worthy of record in view of its rarity. The success of treatment without drainage was an interesting feature.

CASE HISTORY

A Chinese boy aged 6 was admitted to hospital on Sept 16 1946. There was a history of fever and chilliness for ten days and of pain in the right hypochondrium and epigastrium for four days. The mother stated that he had been healthy and had never suffered from any abdominal complaint suggestive of typhoid fever, dysentery, or appendicitis. About ten days before admission there was a gradual onset of malaise and feverishness followed six days later by pain in the right hypochondrium and epigastrium, and the mother discovered a mass below the right ribs. The bowels had been acting normally, and there had been no nausea or vomiting.

His temperature on admission was 102.8° F (39.3° C), pulse 140 and respirations 24. There was slight jaundice of the conjunctivae. On inspection the abdomen, which was slightly distended, clearly showed a round tumour below the ribs on the right side. This moved on respiration and was tender. Examination of the blood showed a leucocytosis of 25,000 per cmm, and a van den Bergh reaction was direct negative, indirect positive. *Ascaris* eggs were present in the stools. He was given penicillin, 10,000 units three-hourly for three days without any effect on his temperature, which continued to swing to 104° F (40° C). This treatment was followed by sulphadiazine, 0.5 g four hourly for five days, also without effect.

Operation—On Sept 24, under open ether and local anaesthesia the abdomen was opened through a right subcostal incision. The gall bladder was found distended, thickened, and roughened but there were no adhesions of omentum or bowel. No stone or worm could be palpated in the cystic or common bile-ducts. The liver was enlarged, but no abscesses were found. The gall bladder was stitched to the parietal peritoneum by a purse-string suture, and opened. 15-20 ml of thick greenish pus was evacuated, and the interior explored by a finger. The gall bladder was closed and 80,000 units of penicillin in 10 ml of distilled water was injected into it. The wound was closed in layers. Examination of the pus showed a pure staphylococcal infection. The day after operation there were signs of consolidation of the lungs, penicillin, 15,000 units three-hourly, was given for three days, after which the patient made an uninterrupted recovery.

COMMENT

Infection of the gall bladder was probably via the blood stream but the presence of *Ascaris* eggs in the stools raises the possibility of a worm having temporarily blocked the cystic duct. However, a case I recently operated on, in which obstruction of the common bile-duct by an *Ascaris* caused severe colic and obstructive jaundice, contrasts with the predominance of fever in the above case.

HAEMATOLOGY

Clinical Hematology. By Maxwell M. Wintrobe, M.D., Ph.D. Second edition thoroughly revised. (Pp. 802, 197 engravings and 14 plates, 10 in colour 55s.) London: Henry Kimpton.

This is probably the world's most accurate and carefully documented textbook of haematology. One can only marvel at the industry and organization which have gone to its making in the midst of the active research work of Wintrobe and his collaborators. It is suited to the professional haematologist and research worker rather than to the general practitioner. The following description of the metabolic changes observed following liver therapy in pernicious anaemia is typical of the author's style.

'The high plasma iron characteristic of pernicious anaemia in relapse drops precipitously even to subnormal values. The protoporphyrin in the erythrocytes, normal or somewhat low in relapse, may tend to rise. The excretion of coproporphyrin I, generally regarded as an index of haemopoietic activity and found elevated during relapse, is restored to normal by specific therapy sometimes after a preliminary increase. Megaloblastic bone marrow has been reported as containing no protoporphyrin. Concomitant with the reappearance of normoblasts following liver therapy protoporphyrin was found in the bone marrow and its quantity increased until just prior to the maximal rise in reticulocytes, following this a lower level was attained. Simultaneous with the reduction of the number of normoblasts in the marrow and in association with the increase of reticulocytes in the peripheral blood, the uric acid content of the blood and urine increases.'

The author discusses metabolism well, and the new chapter on the production and destruction of red corpuscles contains a wealth of information on the chemistry of the manufacture of haemoglobin and the production of red cells much of it obtained by the new tracer technique. In an excellent section on haemoglobinometry he recommends the photoelectric technique (unfortunately wartime British work in this field has not yet been fully published). There is much recent information about folic acid in the megalocytic anaemias and the use of radioactive phosphorus and nitrogen mustards in the treatment of leukaemia and allied conditions, though he does not mention the value of urethane in leukaemia. Some may still wish for a textbook of haematology in which the biochemical and metabolic aspects are less heavily stressed and the morphological, cytological, and genetic factors and the comparative pathology of blood diseases are given more prominence, but perhaps that would be beyond the powers of a single author. The book is well produced, and the last word in the index is the only misprint found.

L. J. WITTS

WATERS OF HIPPOCRENE

Essays and Studies. By W. A. Osborne, formerly Professor of Physiology in the University of Melbourne. (Pp. 188, 10s. 6d.) Melbourne: Lothian Publishing Company Pty., Ltd. 1946.

There is no liberal art which has not been successfully cultivated by some member of our profession. Only Keats indeed, who abandoned practice soon attained the summit of Mount Parnassus, but Beddoes and Bridges are not likely to be forgotten by even exclusive anthologists. Of great prose writers, critics, novelists, and historians we have had plenty. Among those of our faculty who devoted themselves to laboratory rather than clinical science and loved one or other of the Muses, the names of Ronald Ross and Charles Sherrington will be honoured. Prof. W. A. Osborne belongs to this company. His volume of essays and studies includes some excellent papers—for instance, 'Landmarks in Man's Evolution' and 'Eye, Ear, and Finger tip'—which could have been written only by a trained physiologist but their literary form has an artistry that professional allusions sometimes lack. Most of the papers owe little directly to his scientific experience and must therefore be judged beside those of professed men of letters. I think they can abide the trial. His ironical fiction, 'The Garland of Gadara' may not reach Anatole France's level, but it is pleasing. Shakespearean scholars—a quarrelsome tribe—

will no doubt find fault with some of his remarks on the text and its author, the reviewer, however, enjoyed them.

Particularly attractive are the papers which discuss the music of words and the advantages or disadvantages of particular languages. Consonantal alliteration is noticed by everybody, but, Prof. Osborne remarks, vowel resonance has not attracted so much attention, although some famous passages owe much of their beauty to it—for instance, assonance of the broad 'a' in 'A transient and embarrassed phantom,' or of the long 'a' in 'angels and ministers of grace,' or of the long 'u' in 'Arise, shine, for thy light is come.' Our language is supreme in what Prof. Osborne calls 'the magic of monosyllables'—the authorized version of the Bible provides countless examples—'The sun shall not smite thee by day nor the moon by night,' for instance. Shakespeare, whom we are apt to associate with polysyllabic passages, uses chiefly monosyllabic phrases when his characters are deeply moved—for instance Lady Macbeth after the murder. A defect of our language is sigmatism. We all notice the sibilants in congregational hymn singing but our great masters did not always avoid it. The first line of *Paradise Lost* has four 's' sounds. Prof. Osborne points out that Tennyson hated sigmatism and said he would rather have died than written Pope's line, 'What dire offence from amorous causes springs.' Tennyson took great pains to avoid the gagging of geese, 'The Brook.' Prof. Osborne notes is a fine example of his success.

The author discourses on many languages and, as might be expected, knows his Virgil, whose verbal beauty can be loved even by those whose knowledge of Latin is slight. Here are two examples which remain in the reviewer's memory. When Virgil wishes to draw a cheerful picture he uses dactyls—for instance, the helmsman in a clear sky: *Sidera cuncta notat tacito labentia caelo* but when the Sibyl leads Aeneas to the underworld, they move in spondee: *Ibant obscuri sola sub nocte per umbram*. This illustrates another argument of Prof. Osborne—namely the impossibility of an adequate translation from one language into another with a different melody. Any one who cares for verbal beauty will enjoy these essays.

MAJOR GREENWOOD

ADVANCES IN RADIOLOGY

The 1946 Year Book of Radiology. July 1945–June, 1946. Diagnosis, edited by Charles A. Waters, M.D., associate editor Whitmer B. Firor, M.D. Therapeutics, edited by Ira I. Kaplan, M.D., associate editor Sidney Rubinfeld, M.D. (Pp. 464, illustrated \$5.50 or 30s.) Chicago: Year Book Publishers Inc. London: H. K. Lewis and Co.

A year book should give a selection of abstracts of the outstanding contributions from the year's publications, together with editorial comment to guide the less experienced reader. *The Year Book on Radiology* provides such information for radiodiagnosticians and radiotherapists in two distinct parts separately edited. The summaries of the papers are lucid and easy to read, and the illustrations are apposite. The papers chosen from clinical as well as from purely radiological journals are of high quality, and the book will interest others in the profession besides radiologists, the orthopaedic surgeon, neurosurgeon, genito-urinary surgeon, and general physician will find much to stimulate their imagination. The majority of the papers reviewed have been published in journals written in English.

In that half of the journal devoted to diagnosis a successful technique for pneumarthrography of the knee joint is described and illustrated with skiagrams. There is a description of an apparently new syndrome characterized by cortical hyperostosis and intermittent fever in young infants. Diagnostic x-ray findings in all parts of the body are dealt with, as well as plainography, arteriography, and stereoscopic fluoroscopy. Jaffe has reported further on 62 cases of osteoid osteoma, and there are accounts of a case of streptococcal osteomyelitis cured in 10 months by means of penicillin, of the dangers of thorotrast and of intrapulmonary lipiodol, and of tracers in diagnostic radiology. X-rays show that uranium combined with Type I pneumococcus antigen remains attached to it and does not destroy its specificity.

In the introductory section of the part on radiotherapeutics the editor discusses general measures required for cancer control, the relief of pain, the possibilities of super-voltage x-rays,

sensitivity of cephalic myelin to radiation the milk factor in mammary cancer work on chromosome damage, and the possibility of combined thiamine deficiency and high oestrogen activity in causing the cancers of the female genital tract. Radioactive sodium and phosphorus and mustard gas have not been found advantageous in the treatment of cancer. The uses of radiotherapy in various inflammatory and rheumatic conditions are mentioned. The treatment of cancer of the breast, bronchus, stomach, rectum, and uterus by ordinary radiation methods and also the intravesical treatment of bladder cancer by rays are discussed. The account of oestrogen treatment of carcinoma of the prostate emphasizes that it does not cure the condition. There is a report of implantation metastases of a breast cancer at the site of removal of skin for grafting. Other features are the use of the blood coagulation time as a measure of general effects of radiation, articles on radiation physics, the use of radiation in general medicine, neurology, ophthalmology, dermatology, otorhinolaryngology, gynaecology, bone conditions and genito-urinary conditions. A section is devoted to radiation injuries and the uses of radon ointment in their treatment. We must, however, criticize the inclusion of a case of sarcoma of bone said to have been cured by radiation in which diagnosis was confirmed after amputation.

F. ELLIS

SCHEUERMANN'S DISEASE

Die Scheuermannsche Krankheit und ihre Differentialdiagnose
By J. E. W. Brocher, Privatdozent, University of Geneva
(Pp. 91, 122 illustrations, 11 Swiss francs.) Basle: Benno Schwabe and Co., 1946.

The publication of a concise monograph on Scheuermann's disease (osteochondrosis of the spine) is timely, since the condition is being more often diagnosed both clinically and radiologically. The author considers the clinical symptoms and radiological diagnosis in detail and discusses various theories of pathogenesis—without, however, shedding much new light on the matter. He stresses the importance of early diagnosis and recommends that in view of the familial predisposition to the disease children in affected families should be medically supervised. The section on treatment is disappointing and might well have been expanded. The radiographic illustrations are numerous and excellent and since they refer particularly to differential diagnosis, add considerably to the value of the monograph.

PERIPHERAL NERVE INJURIES

Peripheral Nerve Injuries—Principles of Diagnosis By Webb Haymaker and Barnes Woodhall (Pp. 227, 225 illustrations, 22s. 6d.) London: W. B. Saunders Company.

Although Major Haymaker and Col. Woodhall are personally responsible for this book, the United States Army has sponsored its production, and the material for it was collected in army hospitals. The authors have not made a scientific survey of peripheral nerve injuries but have illustrated, from individual cases, the results of different lesions. Their main purpose was to help Service medical officers in the diagnosis of peripheral nerve injuries, but the work is of greater scope than any such guide produced by our Services.

It begins with a detailed and practical account of the peripheral nervous system, and then describes muscle movements and methods of testing them. Some of the techniques differ slightly from those usually employed here, but they are all useful. The clinical description of nerve injuries is clear and readable. The illustrations are an excellent feature of the book—they are as numerous as the pages—and there are photographs of wasted muscles, abnormal postures, sensory markings and sweating tests for every conceivable injury; line drawings are used where photographs would be inadequate. This is an admirable reference book for clinicians who have not had extensive experience of nerve injuries, a sound guide to diagnosis and though not intended for the expert, useful to him in teaching.

DEMIS WILLIAMS

The index of the *Bulletin of War Medicine* edited by the staff of the Bureau of Hygiene and Tropical Diseases has been published by H.M. Stationery Office, price 6d.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Hunterian Society Transactions Vol. IV, Session 1945-6 (Pp. 83, No price.) London: Metropolis Press, 1947.

Prints, lectures on 'The Second Biological Revolution' by Julian Huxley, 'Rehabilitation' by A. H. McIndoe, 'Giddiness' by Parsons Smith, 'Vertigo' by T. Cawthorne and 'Hysteria' by J. R. Rees.

Health Instruction Yearbook 1946 Compiled by O. E. Byrd, Ed. D. (Pp. 399, \$3.00.) California: London: Geoffrey Cumberlege, 1947.

Intended as a reference book for those interested in public health, this book is a review of recent developments and includes many abstracts from the American literature.

Transactions of the American Proctologic Society Forty-fifth annual session (Pp. 621, No price.) California: American Proctologic Society, 1947.

Records a number of papers on proctology and a historical note on 'The First Proctologist'.

Friends in Need (Pp. 75, 1s. 6d.) London: H.M.S.O., 1947.

An illustrated account of the activities of the American British War Relief Society.

Chemical Methods in Clinical Medicine By G. A. Harrison, M.D., F.R.C.S. 3rd ed. (Pp. 630, 40s.) London: J. & A. Churchill, 1947.

New sections have been added on sulphonamide crystals in urinary deposits, aetiology of calculus, analysis of post-mortem blood and cerebrospinal fluid, globin, zinc, insulin and other subjects.

A Short Textbook of Midwifery By G. F. Gibberd, M.S. F.R.C.S., F.R.C.O.G. 4th ed. (Pp. 563, 21s.) London: J. and A. Churchill, 1947.

New material includes discussion of penicillin in puerperal infection and rhesus incompatibility.

Diabetes and Food Rationing 3rd ed. of *Diabetes in Wartime* (Pp. 29, 1s. 3d.) London: H. K. Lewis, 1947.

A summary of diabetic diets and instructions given to patients attending the diabetic clinic of University College Hospital.

The Principles and Practice of Gaseous Anaesthetic Apparatus By A. Charles King, with a foreword by I. W. Murray, C.V.O. D.Sc., M.B., D.A. 2nd ed. (Pp. 47, No price.) London: Bullimore, Tindall and Cox, 1946.

A short account with diagrams of anaesthetic apparatus and its functioning, with notes on the properties of gaseous anaesthetics.

Bacteria in Relation to Domestic Science By C. L. Dukes, M.D., M.Sc., D.P.H. (Pp. 240, 12s. 6d.) Oxford: University Press, Geoffrey Cumberlege, 1947.

An outline of bacteriology for students of domestic science.

The Eye Manifestations of Internal Diseases By I. S. Tieszen, M.D. 2nd ed. (Pp. 614, 50s.) London: Henry Kimpton.

An account of manifestations in the eye of general diseases as well as purely ophthalmic affections. Intended for general practitioners as well as ophthalmologists.

Child Health Edited by A. Moncrieff, M.D., F.R.C.P., and W. A. R. Thomson, M.D. (Pp. 254, 14s.) London: Eyre and Spottiswoode (*Practitioner Handbooks*), 1947.

This book covers the wider aspects of child health, including an account of the health services, preventive measures—such as child guidance clinics, residential schools for handicapped children, school health services and tuberculosis in childhood—as well as four articles on the feeding of infants and children.

The 1946 Year Book of Pediatrics Edited by I. A. Abt, D.Sc., M.D. (Pp. 464, \$3.75.) Chicago: Year Book Publishers, 1947.

A survey of recent advances in pediatrics, including notes on folate, the rhesus factor, and intramuscular sulphonamides.

Annual Review of Physiology Vol. IX, 1947. Editor: Victor E. Hall. (Pp. 736, 36s.) London: H. K. Lewis, 1947.

This book contains reviews of recent advances in physiology in America, Britain, New Zealand, and other countries.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 26 1947

TOBACCO

Whether or not Columbus brought syphilis from the New World to the Old, it appears that he was responsible for the first importation of tobacco. In 1492 an expedition to the island of Cuba came back with the news that the inhabitants perfumed themselves with certain herbs. A Franciscan who went with Columbus on his second voyage (1494-6) described the habit of snuff-taking, and in 1502 Spaniards on the south coast of America described the practice of tobacco-chewing. The exploration of the American Continent uncovered the fact that the smoking of tobacco was universal and immemorial and often associated with tribal ceremonies. A physician, Francisco Fernandes, sent by Philip II of Spain to Mexico, brought the tobacco plant to Europe in 1558. Jean Nicot, the French Ambassador to Portugal, sent seeds to Catherine de' Medici, and his name has been perpetuated in the generic name of the tobacco plant *Nicotiana*. Ralph Lane, the first Governor of Virginia, and Sir Francis Drake initiated Sir Walter Raleigh into the use of what Burton in his *Anatomy of Melancholy* described as "hellish, devilish, and damned tobacco, the ruin and overthrow of body and soul". Some schoolboys may have heard that Raleigh "took a pipe of tobacco a little before he went to the scaffold" and Raleigh's example was responsible for the popularity of tobacco-smoking among the Elizabethan courtiers.¹ So a physician brought the plant to Europe, and an Englishman introduced an old-fashioned American custom—a custom that has prevailed for 400 years in spite of the "counterblaste" of King James I, who described smoking as "a custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and in the black stinking fume thereof nearest resembling the horrible Stygian smoke of the bottomless pit". As medical men we should ask ourselves whether there was not a grain of truth in the declamation of the first Stuart monarch in England. If there is, then according to the Chancellor of the Exchequer "all we need do is smoke a little slower, make cigarettes last a little longer, throw away our stubs a little shorter, knock out our pipes a little later—and all this might even be good for our health".

In reviewing what has been written by doctors on tobacco one cannot fail to notice the marked stress of natural bias. There have been medical men who have approached the subject from a moralistic standpoint. Others, we suspect, have allowed their natural scientific caution to be coloured by a wish not to cast too much discredit on a habit they find pleasurable. At least we can say that no medical man yet appears to have proved that

the consumption of tobacco is good for health, unless we interpret the psychologists' explanation of the smoking habit as a beneficial but infantile assuagement in moments of stress. And we may recall that the late Sir Buckston Browne was firmly convinced that snuff was a useful prophylactic against the common cold.

Tobacco amblyopia is accepted by ophthalmologists as a real thing. Work has been done on the effect of tobacco smoking on muscular performance on peptic ulcer, on post-anaesthetic complications, and particularly on the cardiovascular system. In his Croonian lectures² in 1906 W. H. R. Rivers refers to the observations of Lombard in 1892 that tobacco-smoking depressed muscular activity, but Hough subsequently observed the opposite effect. Rivers concluded that "tobacco comes out from the ergographic test less creditably than the other drugs we have been considering". Most physicians encourage their peptic ulcer patients to cut down smoking, but tobacco enthusiasts received some encouragement from the observations of Jamieson, Illingworth, and Scott³ that there was no correlation between tobacco consumption and severity of symptoms in patients whose peptic ulcers had perforated. H. J. V. Morton⁴ concluded that there was a heavier incidence of post-operative lung complications after abdominal operation in those habitually smoking more than 10 cigarettes or 1/2 oz tobacco a day than in non smokers. The literature on the effect of smoking on the cardiovascular system is extensive, and much of it is referred to in an article by Roth, McDonald, and Sheard,⁵ and in broadsheets issued by the American Heart Association.⁶ Clifford Allbutt, himself a sufferer from angina, described⁷ in 1915 what he called "tobacco angina". He wrote thus of a patient of his believed to be suffering from tobacco angina: "The patient, a strong man of middle life, but presenting some signs of arteriosclerosis, had an attack in my presence. He writhed in a passion of distress, by his wrestling with the invisible foe the sofa on which he was lying was partly overturned, so that from the back of it he rolled on the floor". Allbutt was not only a great physician but a man who used his words carefully and with precision. Neuhof⁸ in 1916 reported a case of sinoauricular block from over-indulgence in tobacco. Briefly, subsequent work with controlled observations shows that smoking tobacco causes a fall in temperature of the hands and feet due to vasoconstriction, an increase of the basal metabolic rate, a rise in blood sugar, a quickening of the pulse, and a lowering of the amplitude of the T wave of the electrocardiogram. These changes are believed to be due to the nicotine and not to the pyridine bases and carbon monoxide also present in tobacco smoke. Another indictment of smoking came from Prof. Raymond Pearl, who gave life tables from the age of 30 for 2,094 non-users of tobacco, 2,814 men who were moderate smokers and 1,905 who were heavy smokers, neither of these last two groups being chewers or snuffers of tobacco. He

found that 45.9% of the non-smokers lived to the age of 70, 41.4% of the moderate smokers, but only 30.4% of the heavy smokers. In commenting on this⁹ we pointed out that Prof. Pearl had stated a correlation but refrained from passing from this to an aetiological conclusion. In a recent issue of the *Journal*¹⁰ we discussed the melancholy fact that nicotine has a depressing effect on fertility.

Mr. Hugh Dalton may well believe that excessive tobacco smoking is incompatible with "a song in my heart." Nicotine comes out of its age-long history as a drug of addiction to which billions of people have shown a fair degree of tolerance. Whether the social and psychological benefits of smoking outweigh the disadvantages of a potent toxin will be for the future historian to decide. But tobacco has now entered a new phase in its history and has become an economic force controlling the destinies of the nation. As an article in the *Economist* of April 12 suggests, it has replaced gold and silver as an international standard of currency. To borrow a phrase from that journal, Mr. Dalton is now trying to take us off the "tobacco standard"—and we agree with him that this might be good for health. And he is, after all, following sound tradition, for in 1604 Parliament imposed a duty of 6s. 8d. a lb. on all tobacco entering England.¹¹ The purpose was to reduce its consumption—"For nowadays this herb (which was formerly used only by the better sort as physic to preserve health) is so excessively taken by disordered persons of base condition that they consume their wages, impair their health and weaken their bodies, and are driven thereby to unthrifty shifts to maintain their gluttonous exercise."

HIGH-VOLTAGE X RAYS

After an interval, due largely to war conditions, it appears that a serious attack is to be made on the medical problems presented by the use of high-voltage x rays. In 1943 Koch, Kerst, and Morrison,¹² at the University of Illinois, showed that the theoretical advantage to be expected is physically attainable. This advantage consists in the enhancement of depth dosage, compared with that at the surface, and its therapeutic significance in relation to the irradiation of deep seated carcinomas is at once evident. Physically, the effect is due to the emission of secondary radiation within the body, so that the total intensity of radiation builds up to a maximum, at a depth characteristic of the initial energy, and then falls off again because of absorption. Working at 20 million volts, the Illinois team found that maximum dosage was at depth of 3 centimetres, and was approximately equivalent to three times that at the surface. It has since been stated¹³ that at 50 million volts the depth for maximum dosage is 10 centimetres, and that the intensity realized is six times the surface value. None the less there has been a dearth hitherto of supporting and detailed information. The experimental material for the Illinois measurements consisted, in effect, of a rectangular block of pressed wood, with provision for the measurement

of radiation intensity at various points within it. Although that was adequate to establish the main point, it is clear that fuller investigations are desirable, comparable for example with those already undertaken by Mayneord and Clarkson¹⁴ at normal x ray energies. The need is indeed all the greater in that x rays of the order of 20 to 50 million volts are therapeutically untried.

The x rays used in the Illinois experiments were obtained from the electromagnetic machine known as the "betatron," for the introduction of which to physical science Prof. Kerst was himself responsible. Medically this has no further significance than as an engineering device for the acceleration of an electron beam to high energies. For use as a source of x rays it is necessary in addition only that a "target" should be provided, impact on which releases the accumulated energy of the electrons. The basic requirement is thus electron acceleration, and apart from such mundane considerations as cost it is immaterial to the radiologist by what engineering methods this is achieved. Such practical considerations cannot, however, be so lightly dismissed in relation to hospital policy. Recent progress in the design and operation of alternative methods of electron acceleration is accordingly relevant from the point of view both of the experimental facilities immediately available and later for the provision of hospital equipment.

A notable step forward was reported last autumn, when it was announced from the Ministry of Supply's Telecommunications Research Establishment at Malvern¹⁵ that the energy level obtainable from a small betatron had been effectively doubled. This was attained by the adoption of the "synchrotron" principle which, during the previous year, had been independently suggested by Veksler¹⁶ in Russia and McMillan¹⁷ in the United States. In brief whereas a "betatron" makes use only of magnetic forces in a "synchrotron" electrical and magnetic forces are employed in combination. And the distinction of the Malvern workers was simply that this laboratory was the first to make a "synchrotron" work. Various alternative methods of producing high-energy electrons are already in the offing. The effect, however, of the Malvern experiments has been to leave the "synchrotron" as the most efficient, and therefore the most economical, that is immediately available. Subsequent progress has, moreover, been encouraging. Within the next few weeks a "synchrotron" capable of producing 12 million-volt electrons, and therefore x rays of corresponding energy, is to be made available for physical and biological tests by a medical research team. This will be a useful step and will give added weight, and no doubt further useful detail, to the information already available. Further progress appears in the main to be a question of engineering. In the United States the General Electric Company has operated a betatron at 100 million electron-volts, and the National Bureau of Standards¹⁸ has completed plans for similar equipment. The latter, together with a 50 million electron-volt betatron, which should be in operation this year, are to be used for the working out of protection

standards for hospital workers. For further installations, however, and for the reason already given, it is to be expected that the synchrotron method will be employed. Here, fortunately, British medicine is more happily placed. Following up its earlier success, the Telecommunications Research Establishment has now designed a 30-million electron-volt synchrotron, and this equipment is already complete, apart from the magnet itself. It should be in operation before the end of the present summer, and it would be a poor compliment to the laboratory's physicists to suggest that any serious degree of difficulty is likely to be experienced.

At this stage, and possibly sooner, a number of policy questions will fall to be decided. The problem is the old one of whether to grasp what is already available or to wait for more. Two different issues are involved—the first, that of the voltage to be used, and the second the physical means to produce it. As to the first, it would be expected that at 30 million electron-volts the greatest x-ray dosage would be at a depth of about 5 centimetres, and that the intensity at that depth would be about four times that at the surface. This is a big enough margin to offer a quite substantial advantage for therapeutic use. Moreover, the evidence is that at such voltages the rate at which intensity falls off at depths greater than the maximum is comparatively slow. The ratio of maximum to surface dosage is therefore the more important figure of the two. And if we can have a four-to-one ratio at once there would seem to be no good reason to wait a further period until the six-to-one ratio, offered by 50 million-volt working, is attainable. It would be equally unwise, however, to go to the opposite extreme and suggest that all major hospitals should at once be provided with 30 million-volt synchrotrons. There is the possibility, on the physical side, not only of further increases in effective voltage but also of new methods which may reduce production costs. Equally, there is a case medically for the obtaining of practical experience at 30 million volts at a limited number of centres before proceeding to any more general programme. And this, it may be expected, will be the line taken.

THE ADRENAL MEDULLA AND HYPERPIESIS

The importance of rare diseases rests in the light they so often throw on normal processes and common abnormalities. Pheochromocytoma is a very rare condition, but its existence shows that there are occasions on which the excessive discharge of adrenaline is capable of causing a rise in the blood pressure and justifies speculation on the part which the adrenal medulla may play in the regulation of the blood pressure in healthy people and in the production of hyperpiesia, both of the malignant variety and of the kind so curiously described as benign.

The usual syndrome produced by pheochromocytomata of the adrenal medulla or of other chromaffin tissue is paroxysmal hypertension, the relationship having been recognized by Von Neussen as long ago as 1897. Two such cases are described in the present issue of the *Journal*. In Spalding's case the disease had after two years progressed so far that the blood pressure was raised for part of the time even between attacks. As a result a condition resembling albuminuric retinitis had appeared. Despite

this, operation produced a remarkable improvement, the blood pressure dropping from such values as 300/205 to 140/100 and the fundi returning almost to normal. Gutman's patient had suffered from paroxysmal hypertension for "several years," and her blood pressure was 300/170 during attacks and 200/120 between. She also suffered the typical ophthalmic changes of malignant hypertension. Although a correct diagnosis was made she died, probably of uræmia, before operation could be carried out. It may be guessed from the changes found post mortem in the kidneys that operation would not for long have prolonged her life. She had already entered the vicious circle of Wilson and Byrom: persistent high blood pressure had produced arterial degeneration, arterial degeneration had given rise to kidney damage, and kidney damage had resulted in accentuation of the hyperpiesis.

It is important to realize that in adrenal medullary hyperpiesis the blood pressure does not necessarily return to normal between attacks. The persistence of the high pressure may be due to a persistent oversecretion of adrenaline. Though some physiologists find this clinical belief difficult of acceptance, Spalding's case affords further evidence of its truth. Should the tumour not be removed we must expect that ultimately kidney damage will take over the job of maintaining the pressure at an abnormal height as in Gutman's case. Early diagnosis is therefore imperative, for if a cure is to be expected adrenalectomy must be performed before the patient has entered the vicious circle. Such early diagnosis is not easy if attacks are rare for they may last only a few minutes, leaving no physical signs to guide the physician who sees the patient in the interim. Suspicion should be aroused by a story of attacks of pallor associated with shivering, perspiration, tremor, breathlessness, nausea, vomiting, a feeling of pressure in the epigastrium, precordial pain, headache, and extreme anxiety. Naturally only a few of such symptoms may be present in the individual case. Sometimes attacks are induced by turning on to the side of the tumour. If the physician is lucky enough to be present during an attack he may find the systolic pressure raised out of proportion to the diastolic. Tachycardia is usual but not invariable, and fibrillation may occur. Hyperglycaemia may be present, though in Spalding's case the blood sugar was lower during an attack than in the interim. The tumour is rarely palpable, but between attacks it may be demonstrable by x-rays after perinephric insufflation.

Much has been written about the possible relationship of the adrenal medulla to common benign hypertension. It has been suggested that the fault may lie with the receptor tissues, which may respond excessively to a normal output of adrenaline, or that inactivation of adrenaline occurs in such cases at an abnormally slow rate. Such speculations do more credit to the imagination of their authors than to their reputation as scientific investigators. Nevertheless it may be said without fear of contradiction that the occasional case of persistent hyperpiesis is found to be due to a pheochromocytoma and that the investigation of hyperpiesis is not complete until this disease has been excluded with as much care as a unilateral renal lesion.

STANDARD SYRINGES

During the war certain foreign sources of supply of syringes were cut off, and manufacture had to be undertaken on a larger scale by British firms. It was in these circumstances that the Surgical Instrument Manufacturers' Association requested the British Standards Institution to prepare British Standard specification for syringes to ensure both

uniformity and an efficient product. This task was begun in 1942, it involved, among other things, research in the Metrology Department of the National Physical Laboratory. The standard specification has now been published,¹ and any syringe conforming to it may in future be identified by the description "B S 1263". As the specification points out, this labelling on the barrel indicates only that the syringe is intended to comply with the specification and is no guarantee that it does so. The specification provides for all capacities, and the use of the word "hypodermic" seems inappropriate in connexion with the larger instruments. There are separate descriptions for all-glass (two-piece) and glass-and-metal syringes. In connexion with the latter it is not required that the cement used for the metal-glass junction shall withstand a certain degree of heat without softening. This requirement, if met, as it has been in certain syringes of Continental make, would save much trouble. The specification deals exhaustively with all dimensions, it is noteworthy that those of the nozzle correspond to the American "Luer" type. The tolerances on capacity—permissible errors in the volume delivered—vary from 0.02 ml for a 1-ml syringe to 1.5 ml for a 50 ml syringe. These may appear generous, but many syringes exceed them. Tests are prescribed for leakage past the piston, with permissible limits for such leakage, and for the tightness of the needle fitting. A "thermal shock" test requires that the barrel "and its permanently attached mountings" shall be capable of being plunged into boiling water without damage. Syringes complying with this specification should be not only more accurate but easier to use, owing to their smoother working and generally better adaptation to their purposes. It is to be hoped that the all-glass type will find more general favour and come into widespread use, particularly in view of the fact that it can be sterilized so much more easily by efficient methods than the glass-metal type. Further specifications are promised for hypodermic needles and for syringes used for special purposes.

POTASSIUM IN DIARRHOEA

The poor results so often obtained hitherto in the treatment of infantile diarrhoea have been due to a false assumption, in the view of Darrow² and of Govan and Darrow,³ that the potassium ion is retained in the cell while the sodium and chloride ions are excluded. These authors suggest that many therapeutic failures have resulted from the belief that it was necessary to restore the normal electrolyte balance only in the extracellular fluids. Recent work has shown that certain cell membranes are permeable to potassium. Darrow and Govan attempt by somewhat complicated calculations to show exactly how much of the body potassium may be lost in cases of dehydration, quite apart from cell destruction. They conclude that in the most severe forms of infantile diarrhoea as much as one-third of the estimated body potassium may be lost. With this in mind they have supplemented the usual oral administration of sodium chloride, lactate, and glucose with potassium chloride. They claim that after giving the electrolyte mixture subcutaneously or intravenously for twenty-four hours they are able subsequently in most cases to give it by the oral route. In addition all very ill patients received blood or plasma transfusion. The reluctance to administer potassium has been largely due to a well-founded distrust of giving an ion that is known at times to have toxic effects. Darrow had no

deaths due to potassium toxæmia, but one patient had heart block, and recovered, there were 5 instances of intense erythema in 50 patients. In 53 cases treated by the old method by the authors there were 17 deaths, in another series of 50 receiving potassium chloride in addition there were only 3 fatal cases. The groups were unfortunately not collateral and were admitted over different periods of the year, so that the observations were not strictly controlled. Nevertheless this line of therapy would appear to be worth serious consideration.

YOUNG THIEVES

Now that juvenile delinquency is receiving belated but fairly purposeful attention from the authorities nothing is so valuable as careful study of the facts. Dr John Bowlby, the psychiatrist in charge of the child guidance unit of the Tavistock Clinic, has had reprinted as a monograph¹ a study, which appeared in the *International Journal of Psycho-analysis* in 1944, of 44 young thieves referred to his clinic. He used as a control group 44 other children who had also been referred to the clinic but who did not steal. The two groups did not differ much in sex, intelligence, or economic status, but the outstanding feature of the thieves was the presence of 9 classified as depressed, 13 as hyperthymic, and 14 of a type which has been called "affectionless". There were no children of this type in the control group, and the affectionless children were significantly more delinquent than the other thieves. All but one were serious offenders, and most of them played truant as well as stole. They constituted more than half of the more serious and chronic offenders, and Dr Bowlby believes that they manifest a true psychiatric syndrome which has hitherto been only partially recognized. Eighteen thieves had a parent or grandparent with serious mental disorder, the incidence was almost identical in the control group, and certainly higher than it would have been in a control group of normal children.

Seventeen of the thieves but only two of the controls, had been completely separated from their mothers or foster-mothers for a long time during their first five years. Significantly, 12 of the 14 affectionless thieves and only 5 of the remaining 30, had suffered a prolonged separation, which is shown to be a principal cause of the affectionless character. Dr Bowlby concludes that prolonged separations are a specific and very frequent cause of chronic delinquency by thwarting the development of the capacity for object-love and hence of the super-ego function. He pleads for combined research on psycho-analytic and social economic factors and for the early diagnosis, treatment, and prevention of the affectionless character. His report confirms the finding of other workers that much delinquency is due to failure of the mother-child relationship. The problem is obviously bound up very closely with that of the neglected child, which has recently come into such prominence.

The Moynihan Lecture in the University of Leeds will be delivered in the Riley-Smith Hall of the University Union at 3.30 p.m. on Monday, May 5 by Dr M. N. Smith-Petersen, Professor of Orthopaedic Surgery in Harvard University. His subject is the evolution of the surgery of the hip-joint. Members of the medical profession are invited to be present.

TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council invites applications for the following Travelling Fellowships for the academic year 1947-8

Rockefeller Medical Fellowships

These Fellowships are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York. They are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £525 per annum for a single Fellow and of £800 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition.

Dorothy Temple Cross Research Fellowships in Tuberculosis

These Fellowships are awarded by the Council from a special endowment of which it is the trustee. The object of the Fellowships, as defined in the trust deed, is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms". The Fellowships will, as a rule, be awarded to candidates who wish to make their studies or inquiries elsewhere than in the United Kingdom. They will ordinarily be awarded for one academic year. The Fellowships provide for the payment of stipend, together with an allowance for travelling and incidental expenses. The stipend will ordinarily be at the rate of £525 per annum for a single Fellow, and of £800 per annum for a married Fellow.

Completed applications for Fellowships of either type must be lodged with the Council not later than June 1. Further particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38, Old Queen Street, Westminster, S.W. 1.

Reports of Societies

CONFERENCE ON SILICOSIS

Health of Underground Workers

A two day conference on silicosis, pneumoconiosis, and dust suppression in mines was held at the Royal Institution on April 16 and 17 under the auspices of the Institution of Mining Engineers and the Institution of Mining and Metallurgy. Seventeen papers were submitted on various aspects of the problem as it affected mines in different parts of the world.

History and Prevention

On the eve of the conference the first Sir Julius Wernher memorial lecture of the Institution of Mining and Metallurgy was delivered by Major-General A. J. ORENSTEIN, chief medical officer of Central Mining, Rand Mines Ltd. His subject was the history and prevention of silicosis, with special reference to the Witwatersrand. He reminded his audience how ancient these diseases were. It had been suggested that neolithic man suffered from them, certainly there were signs of them in a number of Egyptian mummies. The disease was described by Agricola and by Paracelsus, the former mentioning a suppuration of the lung and the role of dust in producing it.

General Orenstein then turned to the silicosis records in South Africa describing the early conditions in the Rand mines and the improvements which had followed the recommendations of the Miners' Phthisis Commission set up by Lord Milner in 1902. This was followed by another commission—wholly medical—in 1911 to inquire into the prevalence of miners' phthisis. Various acts of legislation had been passed with a view to prevention, the latest of them in 1946, the result of yet another commission appointed in 1941. These enactments had not been forced upon the mining industry of the Rand, the directorates and the technical staffs of the mines at least during his own thirty-three years' experience, had eagerly co-operated with the State in means of prevention, and as a result a marked improvement

in the incidence of silicosis had been brought about, but silicosis had by no means been eliminated from the Witwatersrand.

For the purpose of the recent Act, in South Africa silicosis had been defined as any form of pneumoconiosis which was due to inhalation of mineral dust—a very broad definition. Silicosis in South Africa was not interpreted legally as a condition due only to the inhalation of silica or silicate any dust which caused any kind of pneumoconiosis was included in the description.

Discussing the present state of knowledge of silicosis, General Orenstein said that the important causative agent was silicon dioxide silica. The silicate could produce a pneumoconiosis of pathological significance, but it was not so deadly as silica though an exception must be made of asbestosis under certain conditions. Silica damaged the lung by chemical action, and not mechanically, as was thought in the early days. Another reason for the greater danger associated with the smaller particles was that the time during which they remained suspended in the air was in inverse proportion to their size. He went on to speak of various experimental investigations in the prevention of silicosis and methods of dust control. He emphatically endorsed the findings of a committee of the American Medical Association to the effect that although in experimental animals, the prophylactic use of aluminium had been found to inhibit the toxic action of relatively pure quartz, it was not safe to assume, without much more prolonged and careful clinical observation, that this applied to the human subject. Human silicosis generally speaking, evolved much more slowly than experimental silicosis in animals and was often modified in type. Great caution was necessary in the application of aluminium therapy, and it must be stated once and for all that there was no substitute for accepted methods of dust control. The therapeutic use of aluminium in man appeared to relieve symptoms in a very small number of cases but its general application in industry should be delayed until adequately and impartially controlled clinical observation demonstrated its efficacy. No method of prevention should be supported which was likely to push into the background ever so slightly, dust prevention and dust removal.

Pneumoconiosis in British Mines

The conference proper was opened by Mr EMANUEL SHINWELL, M.P., Minister of Fuel and Power. During the past two years, he said, 10,500 coal miners in this country had been certified by the Silicosis Medical Board as suffering from pneumoconiosis. Of these cases 80% came from the South Wales coalfield. The reason for the heavy incidence in South Wales had not been altogether elucidated, and was the subject of intensive research. An interdepartmental committee was about to consider what more could be done. At the same time, this question should not be viewed with despondence. In the technique of dust suppression in coal mines, particularly in methods of wet cutting and water infusion, there were grounds for claiming that Great Britain led the world.

Lord CITRINE, a member of the National Coal Board, presided over a later session, said that from what he had of the mining industry it was evident that the incidence of pneumoconiosis in Great Britain was growing rapidly. It by no means confined to South Wales. The Miners' Welfare Commission was considering certain aspects of rehabilitation of workers recovering from silicosis, though up to the present universally agreed form of rehabilitation had been worked out.

Pathology of Silicosis

The first technical discussion was opened with a paper by Prof. SUTHERLAND STRACHAN, professor of pathology, University of the Witwatersrand, on the pathology of silicosis. He drew attention to the changes which have been observed in the pathological lesions found in the lungs of Rand miners during the last 30 years. In the earlier period the lungs were found at mortem to be large and heavy and to contain large amounts of dust, often showing a true dust pneumonia, with the alveoli and lymphatics packed to capacity with dust. A dense marked degree of bronchitis and emphysema was also present, producing cardiac failure, which was the common cause of death. With the increasing control of dust in the Rand

a more slowly produced silicosis of a simple nature had developed, taking five or possibly eight years to show the first manifestation, with the lungs somewhat larger than normal, chronic bronchitis, a moderate degree of emphysema, possibly discrete silicotic islets, and plaques on the pleural surface. The time taken for tuberculous manifestations to develop had been greatly increased. Silicosis, said Prof Strachan, was in a sense a self-arresting disease. While the man was actively at work, the dust-laden phagocytes continuously accumulated around the silicotic lesions, but this accumulation disappeared some years after the man had been removed from the mines, the lesion was arrested, and no further progress of the disease was likely to take place unless a superimposed infection such as tuberculosis, arose, when a tuberculosilicosis might supervene.

Dr JETHRO GOUGH, lecturer in pathology at the Welsh National School of Medicine, discussed the pneumoconiosis of South Wales coal workers. The disease, he said, had its highest incidence in the anthracite area, was less frequent in the steam coal area, and less frequent still in the bituminous area, though when the disease occurred it had the same characters in all areas. Geological and petrological studies gave no clear explanation of the difference in incidence in different parts of the field. It was an open question whether the quantity of dust inhaled was more important than its chemical composition. He laid stress on the fact that in simple pneumoconiosis of coal workers the amount of fibrosis was small, and that the important change was the focal emphysema, probably due to dust accumulation interfering mechanically with the function of the lungs.

A recondite paper on the action of mineral particles on the lung and the mechanism of their removal was given by Prof A POLICARD of the University of Lyons. One point he made concerned the contrast between 'dead' or inactive dusts and 'young' or active dusts. In the Sahara desert the sand which is 90% silica, is pathologically inert. A flock of sheep, producing a dense dust cloud as it moves, will breathe an extremely dusty atmosphere but the animals never suffer from silicosis. Apparently it is the fresh dust which is noxious. Dust from natural sand is harmless but dust from the same sand when it has been heated is injurious because it is newly split up. Freshly broken particles have a biological activity much greater than old ones.

Dr C M FLETCHER, director of the Pneumoconiosis Research Unit at Cardiff, said that the point as to whether the fibrosis seen in South Wales miners was due purely to overloading the lung with a vast amount of inert dust or to some particular noxious element in the dust—perhaps its silica content—would be borne in mind in a proposed investigation of the remarkable concentration of the disease in South Wales as compared with the rest of the country. Sir MALCOLM WATSON, speaking as a medical man who had had to do with both large scale and small-scale investigation, uttered a warning concerning reliance on animal experiments. Various fallacies were involved if the results of such experiments were taken as analogous to the conditions found in miners who had contracted silicosis. More research was also necessary on the controversial question concerning the role of sericite.

Special Fields

Dr ANTHONY CAPLAN gave a paper on pneumoconiosis in the Kolar goldfield. Dr J M SMITH a review of the work of the Silicosis Medical Bureau at Johannesburg, and Dr W E GEORGE and others on the incidence and prevention of silicosis at Broken Hill New South Wales. Special attention was given to a paper by Dr JOHN CRAW on the control of silicosis in the haematite mines of the north west of England. The haematite deposits in the Cumberland and Furness districts are in two locations, the north mines produce pulmonary fibrosis, the south mines do not. The disease has probably been prevalent for the last forty years—that is to say, before the advent of pneumatic drills. The death-causing factor is infection, usually tuberculosis. In 1935 a new regime was introduced whereby mist projectors were installed to diminish the dust content of the air, and at the same time a complete medical service was set up whereby only fit men were selected for the work, and workmen were x-rayed before beginning employment and periodically thereafter. The results of the combined engineering

and medical control, said Dr CRAW, had been entirely successful, and it was probable that silicosis would cease to be a problem in this locality if the incidence of tuberculosis was strictly controlled. A comparison of the x-ray changes found in miners who had worked under the old conditions and miners who had worked for ten years under the new conditions appeared to be conclusive. Among the old workers a normal x-ray picture was found in 53.3% of the group examined and among the workers under the new conditions in 84.6%.

Aluminium Therapy and Prophylaxis

Dr PETER EDWARDS, medical superintendent of Cheshire Joint Sanatorium, opened the subject of aluminium therapy and prophylaxis for silicosis. He believed that aluminium under proper control could be advantageously used for therapeutic purposes and also, until engineering science had eliminated the dust hazard, as a prophylactic. Only pure aluminium in proper size and concentration should be used, and it was essential that the experiment should be properly conducted and have the support of competent medical authority, as well as of engineers, owners, trade unions, and any Government department concerned, thus preventing any laxity in the conduct of the experiment or immaturity in the assessment of the results. The method of giving aluminium which he favoured was to have a chamber in which aluminium was dispersed by an ejector from a 10 g tin, the chamber on its three sides had 20 openings to permit the attachment of individual mouthpieces for the men under treatment.

Dr DUDLEY IRWIN (United States) said that the problem of silicosis had many facets. It might vary from a disease predominant in the alveoli to a disease predominant in the lymphatics, it varied also with the industry, the department, the plant, and the individual. Aluminium therapy was at best only a second line of defence and when the removal of the dust problem had been surmounted there should be no need for aluminium or any other type of prophylactic. Lieut-Col J R BLAISDELL of the scientific branch of the Field Information Agency B A O R said that the first mine to employ aluminium therapy in silicosis was the Porcupine-McIntyre in Canada, where, over a period of about three years, 54 cases of silicosis were treated by this method, and a number of physiological tests, particularly of respiratory function, were carried out. A good deal of subjective improvement was obtained which was not borne out in the tests. The men felt better, but there was no corresponding improvement in the x-ray findings or the physiological estimations. His feeling was that aluminium probably did not offer much in the case of established silicosis and indeed it was never claimed by the Canadian workers that it was likely to be of great service in that condition but there was every reason to believe that it had a certain prophylactic action.

Dr C L SUTHERLAND, chief medical officer of the Silicosis Medical Board, said that one explanation of the apparent improvement under aluminium was that the substance might have a general tonic effect on the system. It was possible that it relieved the inflammatory thickening of the alveoli or the bronchial spasm, and something might be attributed to the value of the breathing exercises themselves and to the psychological effect. It was intended he said to carry out controlled experiments, but in this country we did not get the type of dust conditions encountered in the United States where this treatment could have a more ready effect nor did we find here—even in Cornwall—the rapidly developing type of silicosis which was most likely to be affected by aluminium treatment.

Dust Suppression and Control

The later papers of the Conference were mostly concerned with ventilation of mines and dust suppression and the sampling of air-borne mine dusts. Mr IVON GRAHAM presented a report on the suppression of dust in the coal mines of Great Britain. Much had been done, he said, especially in South Wales to reduce the average concentration of the dust breathed by the miner. In South Wales pits some years ago concentrations as high as 50 g/1000 cu ft were fairly common in various operations at or near the coal face, and the average was 20 g/1000 cu ft, whereas now the concentration in what were previously

dusty pits was probably not greater than 3 g/1,000 cu ft. In South Wales it was claimed that 99% of the coal faces requiring treatment had been dealt with either by wet cutting, infusion, or hand spraying. Other papers were read on the organization of dust research in South Wales, of which the Mining Research Laboratory, Cardiff, is the centre. Most of the colliery owners have appointed special dust officers, with the status of colliery manager, and there is also a special dust inspector under each of H.M. divisional inspectors. Yet other papers contained an account of similar work carried out in the Transvaal.

After these papers had been read Dr C. M. FLETCHER, who is in charge of the Pneumoconiosis Medical Unit set up under the auspices of the Medical Research Council, made a strong plea for the recognition that in all pneumoconiosis research medical men as well as mining engineers should be called in to co-operate. He failed to find a recognition of this in some of the papers read before the conference. Even in dust suppression, which might be considered to be wholly an engineer's job, the methods and machines were not infallible, they were subject to human control. In the design and functioning of any machine for underground work the human problem should not be overlooked. He regretted that in a plan put forward in South Wales for the appointment of dust officers and others there was apparently no place at all for medical men or biologists. Pneumoconiosis was a disease. Its investigation must be by medical men. The operation of dust control was in the hands of mining engineers, and without their aid nothing could be achieved, but the mining engineer must work in co-operation with the doctor in the design of his methods and the assessment of his results.

The National Coal Board

A very lively and fruitful conference closed with an address by Dr IDRIS JONES, director of research, National Coal Board. He said that it still remained to be established whether the concentration of dust was more important than its chemical composition. Dust suppression devices should be incorporated as a matter of routine in the manufacture of mining machinery. The potentialities of foam and wetting agents must be studied and new instruments developed for sampling and recording of dustiness and for rapid size analysis both underground and in the laboratory. The National Coal Board had these and many other problems very much in mind. This was part of their job as custodians of the nation's collieries and as employers of labour. The scientific department of the Board was still in its infancy, but it was getting to work. The dust officer organization in South Wales was being further co-ordinated, new machines and working methods were being examined and new devices tried out. One of the Board's research directors was concerned with the human problems, and part of his task would be to ensure the closest possible liaison between the engineers and the Medical Research Council workers. The primary object was to ensure that every possible help was given to the medical researchers. The Board had no vested interest in dust; its concern was to get rid of it, and anyone who could contribute from any side towards this end would have the Board's full support.

Long before the bombing of Pearl Harbour brought America into the war her citizens, with characteristic generosity, were providing Britain with all kinds of equipment—mobile kitchens, clothes, medical necessities and even seeds for allotments. *Friends in Need* (H.M.S.O., 1s 6d) tells the story of the British War Relief Society of America. The B.W.R.S. was formed as early as October, 1939, eventually it had established over 900 committees, covering every state in the U.S.A. with the two main committees in New York and London. It sent a total of £12,000,000 in cash and kind to Great Britain, the first shipment arriving in February, 1940. When London was bombed later that year "the stream of relief became a flood," and a special committee to deal with air-raid relief was established. Besides directly benefiting nearly every hospital in Britain the society provided six elaborate X-ray installations for emergency war hospitals, set up and maintained a radon centre, completely re-equipped the Hadfield Spears Field Hospital, and equipped and financed the Churchill Hospital in Hampshire. This attractively illustrated pamphlet is both a catalogue of unsurpassed generosity and a historically interesting survey of many wartime welfare services.

Correspondence

Control of Leprosy

SIR—Dr C. J. Austin (April 12, p. 506) quotes from your leading article of Nov. 2, 1946, a sentence on the injurious effects of compulsory isolation of leprosy patients. As that article dealt mainly with my address of last year before the Royal Society of Arts—a full abstract of which appeared in your issue of June 1, 1946 (p. 825)—may I once more point out that what I have repeatedly condemned as "worse than useless" is the indiscriminate compulsory isolation of *all types of leprosy*, including a very large proportion of uninfected neural ones, with consequent hiding of nearly all the early cases until their disease has become too advanced to be amenable to treatment and they have infected members of their households. Happily, during the first quarter of a century that plan has nearly universally been modified to allow early and uninfected cases to be treated as out-patients, at about one hundredth of the cost of isolation.

As a matter of fact, as early as 1925—in an unpublished memorandum which has served as a basis for the work of the British Empire Leprosy Relief Association—I wrote "No hard and fast rules can be laid down to cover every area. Fiji, with its numerous scattered islands, is an exceptional case and I am well aware of the good work done there by the late Dr. Neff and by Dr. Austin. I am also in agreement with commendation of that work in an annotation in your issue of March 10, 1945 (p. 338)—I am, etc.

London NW 3

LEONARD ROGERS

Malayan Medical Service

SIR—The Colonial Office intends soon to recruit a large number of doctors to the European staff of the Malayan Medical Service, and there are several important facts which might be published for the benefit of readers who are considering the attractions of this service.

The greatest shortage of medical officers in Malaya is at present in Singapore and it is to this town that the majority of recruits will be posted. The intending candidate will be informed at his interview that the salary will be more than adequate for all his needs in spite of the difficult conditions in Malaya. He will also be told that if a particular branch of medicine interests him he will be encouraged to develop his interest especially if he intends to study for a higher degree in his subject. But on arrival at Singapore the newcomer will find that his salary will meet vital expenses only if he exercises the strictest economy, should he be married and have any children, then it will be absolutely impossible to meet expenses from salary alone.

As regards his work, I can assure him from bitter experience he will not be encouraged to follow the branch of medicine which interests him. He will be sent from one unsatisfactory task to another. If the recruit protests on these two points and asks for a transfer up country where living is much less expensive and the work more satisfactory he will be refused and asked as I was, "What sort of service would this be if juniors were allowed to do only the work which interests them?"

Also of great interest to the recruits is the proposed amalgamation of the present Malayan Medical Service, which comprises mostly doctors recruited from Great Britain, with the local service which comprises graduates of the medical school at Singapore. The latter at present are not eligible for the higher posts except when they are promoted to the Malayan Service, and it is proposed now to give both the local graduate and the graduate from Great Britain equal rights to promotion—a welcome change which has been long overdue.

The morale of the medical service in Malaya is very bad. The local graduates have no faith in the present administration and already two thirds of their total number in the service have resigned. Many of the European doctors would also resign were it not for the fact that in the case of the older men the loss of pension rights added to their already too heavy financial burdens would place them in an impossible position.

and in the case of the younger men the financial penalties imposed on them if they resign before the end of the three years probationary service are too great for their slender resources

Those who intend joining the service must know that there is grave discontent among medical officers in Malaya and that this discontent is amply justified. They must also realize that they can place no trust in the truth of statements concerning conditions of service in the Colonies made to them at their interview in London. These are not the complaints of an inexperienced person who takes badly to service conditions, for I have already had six years with the Navy and am well used to the discipline of that Service. Nor are they those of one who dislikes hard work in a hospital. They are the bitter complaints of a man who resigned after six months in the Malayan Medical Service and who has seen his plans for the future destroyed by the deliberate misrepresentations of a supposedly responsible Government Department—I am, etc.,

Singapore

R O KANE

** The Colonial Office informs us that a commission to investigate salaries in the Malayan Medical Service has now arrived in Malaya—ED B M J

Tuberculosis and the NHS Act

SIR—We may expect to see the personnel of the regional boards published at any moment, and as soon as appointed they will have to get to work on the new organization due to operate from April 1, 1948. We also note that the Minister of Health himself is to give an address on July 8 at the Commonwealth and Empire Health and Tuberculosis Conference, arranged by the National Association for the Prevention of Tuberculosis, on the National Health Service Act and its Effect on Tuberculosis Schemes.

Tuberculosis, because of its effect not only on the patient but on the community, presents special problems and difficulties as is generally admitted, we note that the Minister of Health and Minister of National Insurance have accepted the position that pulmonary cases will qualify for extra benefits, and the Ministry of Labour is planning special workshops for the tuberculous. No scheme for the prevention and treatment of tuberculosis can ever be efficient and effective unless the family is regarded as the unit. If separate medical staffs undertake separate parts of what should be a unified tuberculosis scheme, then we shall surely see return a state comparable with the pre-Astor-report days.

Leading officials of the Ministry of Health have stated that it is the full intention to continue the best features of efficient tuberculosis schemes. How, then, can we ensure within the framework of the new Act the greatest possible integration of the several components which ought to constitute a workable and successful regional organization? May I set down my views to achieve this end?

1 The Minister of Health, after consultation with central health services council should have a tuberculosis advisory committee to advise on policy and to provide technical guidance on tuberculosis, such course being permissible by Section 2 (3) of the Act.

2 For the control and direction of the day-to-day tuberculosis work of diagnosis and treatment there should be appointed by each regional board a tuberculosis committee to be assisted by a regional tuberculosis officer and staff. The committee could take the form of (a) selected members of the regional hospital board, with co-opted persons of experience in tuberculosis or (b) an advisory technical body of mainly tuberculosis officers and medical officers of health, or (c) in large regions, both (a) and (b)—that is, a tuberculosis committee aided by a technical body.

3 The tuberculosis medical staff for each region should consist of one or more graded medical teams with clerical assistance and tuberculosis health visitors who would assist in the dispensary work and bring a first hand knowledge of the family circumstances and conditions and contacts—so important in a scheme based on persuasion. Each team could be given responsibility for an area containing several hundred thousand population, and preferably co-extensive with one or two hospital management committee areas. The teams should perform both dispensary and sanatorium duties, work in the closest relation with the general practitioners, examine contacts, and be given the definite duty to assist the medical officers of health of county and county borough councils in care work and in preventing the spread of infection. Each team should have a

register of all the tuberculosis cases in their area, and generally hold the tuberculosis service together so that they would always know what is happening to the patients, both pulmonary and non-pulmonary.

4 Throughout the country there are many small tuberculosis institutions, it is the intention gradually to eliminate these as separate units and to provide equivalent accommodation as part of the large and improved general hospitals. They may take a long time. Meantime how should the day-to-day management of the existing sanatoria be effected? I suggest that they and the tuberculosis dispensaries be taken as a group in each region and administered by the regional tuberculosis committee, which could and should co-operate where advantageous with hospital management committees in the region.

The proposed transfer of the whole hospital and specialist services on April 1, 1948, will involve (along with general medical, dental, pharmaceutical, ophthalmic, etc., services) a considerable feat of organization, in the event of delay, and if the date fixed cannot be amended, I suggest that the county councils and county boroughs be asked to continue by contract the tuberculosis service on behalf of the regional boards until the transfer can be made on a well-planned basis—I am, etc.

G LISSANT COX

Intra-group Transfusion Reactions

SIR,—One of the problems in connexion with iso sensitization to the Rh factor that still awaits clarification is why transfusion reactions due to this cause were not recognized till 1939, when Wiener and Peters encountered three cases following transfusions of blood of the homologous groups. It cannot be said that opportunities for iso-immunization were not frequent. Previous to the discovery of liver therapy for Addison's anaemia repeated blood transfusion was the only effective treatment. It is seen from the reports of the British Red Cross Blood Transfusion Service relating to this period that approximately one patient in five that was transfused was a subject of pernicious anaemia.

The demonstration of anti-Rh agglutinins by the rapid slide test of Diamond and Abelson would seem to throw some light on the cause of the delay in the recognition of intra-group transfusion reactions. In this test ovalated undiluted blood is used instead of a dilute suspension of red cells employed in the tube-agglutination test. The use of a 2% suspension of red cells in routine blood grouping and cross matching has now become the standard technique in every blood bank and laboratory. The advantages claimed for this technique are that it helps iso agglutination to develop promptly by providing optimal conditions, and also prevents errors due to false agglutination. Concentrated blood on the other hand tends to mask a weak reaction.

It will be remembered that, previous to the adoption of the tube method, whole blood or defibrinated blood was almost exclusively used for blood grouping and cross matching purposes and that the tests were performed on a tilt or slide. Very often the drop of blood was transferred to the drop of grouping serum (or recipient's serum) direct from the finger-prick by means of a platinum loop. I saw this rapid test done on a porcelain tilt by Dr H F Brewer, medical officer of the British Red Cross Blood Transfusion Service, at St Bartholomew's Hospital, London, in 1932.

It will be seen that the Diamond-Abelson test for Rh iso sensitization does not appreciably differ from the blood-grouping and direct-matching technique followed in the earlier days. Is it possible that incompatibilities were encountered and donors though of the homologous blood groups, were rejected, although the true explanation for the anomalous reactions was not known? The answer would seem to be in the affirmative. In a plea for a national blood transfusion conference made by P L Oliver, founder and honorary secretary of the British Red Cross Blood Transfusion Service (*Journal* Nov 21, 1936, p 1032) one of the problems suggested for consideration was "cross grouping of donor against patient". The following statement is found under this heading: "During the past eight months 78 donors have been found to be incompatible against patients of their own group. This has been found especially prevalent in Group I (Moss)". Whether they were all due to subgroups or to some other cause it is difficult to say. But it is clear that intra-group incompatibility was a problem for serious consideration. It was naturally a problem to the service rather than to the clinicians.

There can be no doubt that the change in the technique from the use of whole blood to diluted blood was directly responsible

sible for bringing down the sensitivity of the direct matching test by almost one-half. It was apparently not suspected that the use of dilute blood would interfere with agglutination of the red cells sensitized by the "blocking" or "incomplete" antibody.

I have been prompted to point out the similarity between the Diamond-Abelson test and the direct matching test as it was performed in the 'thirties as a possible explanation for the non recognition, or perhaps non occurrence, of intra-group transfusion reactions due to the Rh factor and not to bring any discredit whatever on the value of the test. Indeed, to us in India, where anti-Rh serum is so hard to obtain, the test has been a real boon as it enables the detection of intra group incompatibility in the absence of anti-Rh serum and also helps to select a compatible donor. And that is what the clinician is interested in—I am, etc.

Retrodisplacement and Fertility

SIR—Whenever a man states that there is 'no shadow of doubt' about an assertion one may know that even he suspects its truth. Dr Bethel Solomons (April 5, p 465) asserts that

There is not the slightest doubt that retrodisplacement of the uterus is a cause of sterility. Had he stated that retrodisplacement is frequently associated with lowered fertility there would be less reason to disagree with him.

Some people with retroussed noses have nasal obstruction, but one should not assert that retroussed noses cause nasal obstruction. On the other hand damage to the nasal septum may produce both nasal obstruction and a retroussed nose. It will not cure the nasal obstruction for a plastic surgeon to build a Roman nose, and the obstruction is usually relieved without altering the curve of the external organ.

Retroversion is one of the normal positions of the uterus, though less common than anteversion. Lowered fertility is a frequent concomitant of uterine hypoplasia, and the hypoplastic uterus is very frequently either acutely retroflexed or acutely anteverted, but it is a bold statement that the position of the uterus causes the failure of conception. To put the uterus in another position will not cure its imperfect development, and as a matter of practical experience does not cure infertility—I am, etc.,

FRANK STABLER

Reiter's Syndrome

SIR—In the interesting annotation on Reiter's syndrome (April 12, p 495) it is noted that this condition is apparently confined to young adult males.

Two cases occurring in women have been described. Details of one are given by Dr A. Touraine under the title of "pseudogonococcie enteritique" (*Ann Derm Syph*, Paris, 1946, 6, 687). The other case, described by W. Lever and G. M. Crawford (*Arch Derm Syph*, Chicago, 1944, 49, 389), is cited by A. Touraine and A. Ruel in a very comprehensive survey of the subject (*Ann Derm Syph*, Paris, 1946, 6, 61)—I am, etc.,

London SW1

JAMES MARSHALL

SIR—I read in your annotation (April 12, p 495) that Reiter's disease is apparently confined to young adults.

It might be of interest to report that three months ago I attended a man of 58 who had this disease. It began with painful haematuria following in three days with bilateral conjunctivitis and two days later an arthritis of the right ankle. The urethritis cleared in a week and the conjunctivitis in five days, but the arthritis became increasingly painful, and both knees were affected ten days from the onset of the original symptoms. Eventually his only relief was from diathermy and spa treatment. This man had no venereal history, nor had he ever had any dysentery. Four years previously he had had arthritis in the right knee, and presumably this had left him susceptible to a recurrence of arthritic symptoms—I am etc.,

Hales Owen, Wores

G T NEWTON

Curare

SIR—Having followed the recent correspondence on the condition of shock and respiratory depression associated with the use of curare, commencing with a letter by Dr Massey Dawkins (Jan 18, p 111), with considerable interest, it is felt that the following points are pertinent.

Respiratory depression caused by anaesthetic agents, whether due to their action on the respiratory centre or on the respiratory musculature, is associated, first, with an increase in the CO₂ tension and, secondly, with a decrease in the O₂ tension. To understand this it is necessary to realize the underlying physiological facts. The optimum number of respirations for elimination of CO₂ with a tidal air of about 500 ml is approximately 16 per minute in a person having a normal basal metabolic rate. However, the amount of oxygen available for normal tissue respiration is four times the value necessary, so by this it can be seen that the important factor in respiratory depression is CO₂ accumulation and not anoxaemia. CO₂ accumulation when about 7% causes a rise of blood pressure through its central action on the vasomotor centre, at lower concentration the CO₂, having a peripheral dilating effect on the arterioles, causes the central effect to be counterbalanced.

Some interesting work has recently been published by R. D. Dripps in America (*Anesthesiology* 1947, 8, 15), where he has shown that a fall in blood pressure following cyclopropane anaesthesia is associated with a high CO₂ tension in the blood during operation. This also is probably the mechanism of the condition of shock occurring after the use of curare where marked respiratory depression has occurred without adequate CO₂ elimination. In using curare I have made a practice of not administering it within half an hour of the expected termination of an operation, but if increased relaxation is required I increase the concentration of the anaesthetic agent I am using and so avoid causing respiratory depression lasting from 15 to 30 minutes.

With this CO₂ accumulation theory in view I do not ever add CO₂ to the anaesthetic mixture, but if there is not a good respiratory exchange at the closing stages of the operation I give a few minutes of "aided" respiration by pressure on the reservoir bag, having first "blown off" the anaesthetic gases.

Since having followed this routine I have had no cases of shock following curare administration, except on one occasion when I found I had been using non acting soda lime in a closed circuit apparatus—I am, etc.

Leamington Spa

GEOFFREY L. WAY

SIR,—In his letter dealing with the post-operative anoxaemia allegedly attributable to the use of curare, Dr W. M. Maidlow (April 5, p 466) invokes total carbon dioxide absorption in closed circuits as a more culpable factor. In support of his contention that absorption should be but partial or intermittent he asserts that "the carbon dioxide in the circuit causes dissociation of oxygen from oxyhaemoglobin in the tissues." The italics are mine, and I would submit, Sir, that what promotes the dissociation of oxyhaemoglobin in the tissues is the carbon dioxide tension in the tissues. This tension is normally higher than that in the alveoli. Under resting conditions the relative figures are 46 and 40 mm Hg. If this normal carbon dioxide tension gradient is reversed, by either incomplete absorption or the addition of carbon dioxide artificially to the inspired gases, it becomes easier for the oxyhaemoglobin to dissociate in the lungs than in the tissues, and the blood leaves the lungs having secured rather less oxygen than it would otherwise have done. In fact the tissues have not been 'given the benefit' which was intended. Left to themselves the tissues will by their own respiration build up a local carbon dioxide tension conducive to oxyhaemoglobin dissociation, and we can raise that local tension only at the expense of a similar rise in the alveolar tension—the old dilemma of the swings and roundabouts.

It is true that any patient in first- or second plane inhalation anaesthesia will breathe less deeply if he is put into a circuit with total absorption, and if the atmosphere he was breathing was just sufficient to maintain oxygenation he will now become anoxic. But since it is the usual practice to use oxygen enriched atmospheres in closed circuits this situation does not arise during

maintenance It is, however, advisable towards the close of the anaesthetic gradually to admit air to the circuit and simultaneously to allow slightly less absorption, so that the patient leaves the theatre with alveolar nitrogen and carbon dioxide tensions as near the resting normal as possible and is less likely to have the depressed respiration which is almost as bad for his ward sister as for him

Dr Maidlow also holds that the use of an endotracheal tube necessitates the use of more curare to relax the larynx I would suggest that cocaine would make the larynx more tolerant of the tube without predisposing to post-operative respiratory depression—I am etc,

DONALD V BATEMAN

d-Tubocurarine

SIR—May we, as manufacturers of *d* tubocurarine chloride, comment on the paper by Dr Gordon Ostlere (April 5, p 448)?

Nomenclature of Curare Preparations—We suggest that in order to avoid confusion the general term "curare" should not be used as it has been in the past when referring to preparations of the drug "Curarine," as originally issued by us, was solid crystalline *d*-tubocurarine chloride For the convenience of the profession this has been replaced by "tubarine," an aqueous solution of *d*-tubocurarine chloride

Sterility—The extemporaneous preparation and sterilization of solutions containing *d*-tubocurarine chloride is no longer necessary, as tubarine is a sterile solution Attempts to sterilize *d*-tubocurarine chloride solutions by heat will probably cause a partial decomposition of the salt, this may account for some of the variations in response reported and possibly for some of the side-effects

Stability—Ostlere states that "The potency of these preparations remained fairly constant as long as required, in some cases up to six months It is not clear whether he is referring to all the preparations he lists or only to the solutions made up by him The method of preparing tubarine ensures its stability over considerable periods under normal conditions of storage

Curare Preparations and Hypertension—In the same issue of the Journal (p 445) Drs J A Hobson and Frederick Prescott describe their experiences with tubarine in electric convulsion therapy They noted no spectacular rises in blood pressure, and, in fact, they deliberately included hypertensives in their series without untoward results We do not consider that hypertension *per se* is a contraindication to the use of tubarine either in electric convulsion therapy or general surgery In the well-ventilated patient undergoing an operation with relaxation secured by tubarine the blood pressure rarely rises more than 10-15 mm Hg (Prescott, F, Organe, G, and Rowbotham, S, *Lancet* 1946, 2, 80)—I am, etc,

JOHN CURTIS

Burroughs Wellcome and Co
London NW 1

Tubocurarine and Blood Pressure

SIR—I was interested to note that Dr Gordon Ostlere (April 5, p 448) reports that blood pressure very commonly rises after the administration of curare The early work on this subject (Griffith) shows no effect on the heart and no rise or fall in blood pressure

I have of necessity used curare in an open or semi-open circuit and have stepped up the oxygen percentage to 50 or more By this means, with or without squeezing the rebreathing bag, it is possible to keep the patient well oxygenated, but it is more difficult to ensure that one is giving the patient a flow of mixed gases of at least 5 litres a minute I think that the explanation of the increase in blood pressure noted may in some cases be due to a rise in blood CO₂ content due to diminished pulmonary ventilation and in the absence of precise evidence to the contrary not attribute this vasopressor action to curare or tubarine I have myself noted a rise of blood pressure from 150/100 to 180/120 at the end of an operation for closure of perforated gastric ulcer I used a somewhat similar technique to that described by Dr Ostlere, and the patient's colour and general condition were good, but there was then paralysis of the intercostal muscles The blood pressure became normal

(140/100) after artificial respiration I shall be interested to see what blood-pressure changes have been recorded by anaesthetists using tubarine in a closed-circuit machine with CO₂ absorption—I am, etc

Newport Mon

K STEVENSON THOM

Pethidine

SIR—The communication by Miss Josephine Barnes (April 5, p 437) on the use of pethidine in labour is of interest to the staff at the County of Lanark Maternity Hospital and the Motherwell and Wishaw Hospital, where the administration of pethidine during labour has been a routine practice for over two years During that time 4,000 cases were given this preparation, with beneficial results in most instances The effects of the drug were similar to those so accurately described by Miss Barnes

Miss Barnes noted that effective analgesia was experienced by 55% of the patients My impression is that a higher percentage would have been gained by giving larger doses of pethidine At one time we also administered it in quantities of 100 mg, but we found that greater benefit could be obtained by increasing the dose to 200 mg It is a preparation which every practitioner should include in his obstetrical outfit—I am, etc,

Bellshill Lanarkshire

SAMUEL J CAMERON

Safety in Electric Convulsion Therapy

SIR—In their article (April 5, p 445) on the use of *d*-tubocurarine chloride and thiopentone in electric convulsion therapy Drs J A Hobson and F Prescott have discussed the question of additional therapeutic procedures which they claim to lessen the incidence of the traumatic complications of this treatment They have sought, therefore, to minimize these risks by the use of curare, and, because this substance produces subjective sensations at least as terrifying as leptazol, have been driven to anaesthetize their patients with thiopentone as a preliminary Surely a case can be made for adopting a more practical view of the traumatic risks of ECT In my experience, if the patient is placed on a firm surface with a small horse hair pillow under the thoracic spine, no mechanical restraint is necessary and compression fractures of the spine with symptoms of pain in the back are almost unknown X-ray photographs show that under these conditions both lumbar and dorsal spine are in very slight hyperextension A lumbar pad merely increases the extension of the lumbar spine without altering the position of the thoracic spine unless the pad is very large If these fractures were likely to produce later disability, we should surely by now have heard of some in the eight years that have passed since ECT was commenced at this hospital, but none have so far come to our notice Such risks from fracture must, from the patient's point of view, weigh lightly when compared with the much more serious risks of curare and thiopentone Indeed, the authors admit that four deaths have so far been reported in the literature from curare-controlled convulsions

Drs Hobson and Prescott further claim that a rise of blood pressure is prevented by curare For the normal individual this is not important, occurring as it does in ordinary exercise while the work of American authors has shown how well hypertensive patients tolerate ECT Finally, it is claimed that the unpleasantness of ECT is eliminated If this is all that is desired, then it seems that thiopentone alone would be sufficient but let us recognize that ECT, properly carried out with modern apparatus, is not particularly unpleasant and that most of our patients complain not of the treatment itself but of the loss of memory and confusion that sometimes follow In this sphere much can be done with co-operative patients in explaining that these temporary symptoms may be expected

A therapeutic diagram can be drawn which is a complete circle of medication If we start with a convulsant drug, such as leptazol, fractures are controlled by curare, while curare is controlled by thiopentone In the event of an overdose of thiopentone, we come back to the convulsant for its antidote One wonders what therapeutic heights will be reached if this crescendo of medication is allowed to continue—I am etc

Worthingham Surrey

RONALD ARTHUR SANDISON

International System of Weights and Measures

SIR—In his letter (April 19 p 545) Mr Oliver Stewart says that in my article on 'The International System of Weights and Measures' I argued that because there is no whole number relationship between the metre and the kilogram and the litre these last two are no longer part of the metric system. I did not say this. What I did say was that the kilogram and litre have now no connexion with the metre and consequently to apply the term metric to them is misleading.

Mr Stewart says that the description metric is justified on the ground that it is a metonymy, but even if it were a metonymy one should avoid using a figure of speech when, as in this case, it misleads. One of the reasons why I discussed the title for the system was that opponents of the system in the United States have already drawn attention to the error of calling the system metric when in fact it is not. Let us heed this criticism and not lay ourselves open to it in our turn. Mr Stewart's objection to the description International System on the ground that it is unfamiliar is interesting. None of us who learnt in our youth the old system felt comfortable at first with unfamiliar millilitres, but none of us, I hope, would let unfamiliarity impede reform or let mental inertia gain a victory over mental integrity. What is now strange and unfamiliar will become ordinary and familiar to the rising generation.

I am glad that Mr Stewart is succeeding in his efforts to familiarize aviation circles with scientific methods of measurement and it is gratifying to learn that the International Civil Aviation Organization has adopted the appropriately named International System of Weights and Measures—I am, etc.,

London W 14

J M HAMILL

Child Guidance

SIR—Dr J A McCluskie's letter (April 12, p 508) contains several assertions which should be of interest to many psychiatrists and general practitioners. First Cases should be referred to the child psychiatrist, and then what happens will depend on where the child lives. This appears to me to be sensible and practical, and a sufficient answer to Prof Cyril Burt and the Nuffield Committee for the present time. One hopes however that it will become possible in the future to see that no child is denied the best form of help because of geographical factors. Secondly 'Only an experienced general practitioner knows sufficient of the intimate life of people to make eventually a really good child psychiatrist.' While this is rather sweeping I am prepared to support it to a great extent. For this reason, rather than the one put forward by Dr McCluskie I am also perturbed about the tendency to 'drive more child guidance into the out patient departments of mental hospitals.' It would be interesting to learn what percentage of practising psychiatrists to-day have had more than say six months' experience in general practice.

In this approaching new era of medicine when one understands that doctors will be classified and ranked, I suggest that no doctor should be given the status of specialist unless he has done a minimum period in general practice. In the specialty of psychiatry this period should be longer than in others, with perhaps child psychiatry necessitating the longest period—I am, etc.

REIGHTON

S SHARMAN

Correction of Medical Register

SIR—I am desired by the returning officer to say that voting papers for the purpose of the forthcoming election of one member of the General Medical Council to represent the registered medical practitioners resident in England were issued on April 22 to all practitioners having registered addresses in England, and that the authorities of the Council would be glad if any such practitioner who has not received a voting paper would communicate immediately with the office of the Council (44, Hallam Street London, W 1) whether or not he proposes to vote in the election in order to ascertain that his address is correctly entered in the *Medical Register*—I am, etc.,

London W 1

MICHAEL HESELTINE

Obituary

C LOUIS LEIPOLDT FRCS

We announce with regret the death on April 14, at the age of 67, of Dr C Louis Leipoldt, who was for many years editor of the *South African Medical Journal* and secretary of the Medical Association of South Africa. Dr Leipoldt was a remarkable personality. His reputation as a medical editor as a war correspondent, poet, and gourmet extended far beyond the bounds of his native South Africa.

Christian Fred Louis Leipoldt was born at Clanwilliam Cape Province, in 1880. He had no formal schooling but was educated by his father, who, like his grandfather was a missionary. After matriculating he joined the staff of the *South African News* in Capetown and was war correspondent during the South African War for a number of European newspapers. His literary career had begun rather earlier when he won a prize for an essay in the *Boys Own Paper*. At about the same time he had contributed to the correspondence columns of the *Cape Times*. His views and his way of expressing them so impressed the editor that Leipoldt was invited to visit the office. By 1902 Leipoldt was roving around Europe as a free-lance journalist, work which ended when he became a student at Guy's Hospital. He qualified MRCS, LRCP in 1907, studied for a while at Berlin and Graz and took the FRCS in 1909. A few years later he returned to South Africa. The record of his work as a pioneer medical inspector of schools in the Transvaal is to be found in *Bushveld Doctor* which was published in London in 1937. By 1919 Leipoldt had been appointed medical inspector of schools in Cape Province, but in 1923 he joined the editorial staff of the Pretoria newspaper *Die Volkstem*. Later he again left journalism for medicine and set up in Capetown as a paediatrician. His interest in this specialty continued and he was made a corresponding member of the British Paediatric Association in 1935.

In 1927 Leipoldt was appointed organizing secretary of the Medical Association of South Africa and at the same time with Dr W Darley Hartley, he became joint editor of the *Journal of the Medical Association of South Africa (BMA)*. The publication of the first number of this new journal on Jan 8, 1927, marked the successful outcome of efforts which had been made over several years to combine two medical associations and two journals, the *South African Medical Record* and the *Medical Journal of South Africa*. The union of the two associations and its establishment as an integral part of the British Medical Association owed much to the statesmanlike efforts of Dr Cox. In the following year Dr Leipoldt was one of the South African representatives at the meeting of the Representative Body at Cardiff.

Dr Leipoldt continued as editor of the *Journal of the Medical Association of South Africa* later the *South African Medical Journal* until the end of 1944, when he was succeeded by J S Du Plessis. He pointed out at one time that the policy of his journal was 'the policy of the Medical Association of South Africa on all questions whereon the Association in the interests of the practitioners of this country speaks with the consensus of its members. He added, 'That ideal does not exclude editorial responsibility, nor does it bridle editorial initiative, but it strengthens and enlarges both.' When Dr Leipoldt retired from the editorship his successor paid a farewell tribute to his 'few idiosyncrasies' as well as to his 'great and many virtues'.

Leipoldt cultivated a natural taste for food and wine, and one of his well known foibles was to proclaim that wine was infinitely more beneficial than milk, which he was inclined to distrust. Among other accomplishments he was a good cook, a keen botanist, and a student of bird life.

Leipoldt's main interests were in literature and in medical science. He wrote fluently and elegantly in either Afrikaans or English, and in 1936 he published a biographical study of Jan van Riebeeck, the first commander of the first white settlement at the Cape of Good Hope. Leipoldt will be remembered by medical men as an editor and as a devoted servant of the Medical Association of South Africa. He will be remembered

by many others for his contributions to literature and more especially to the Afrikaans literature. His tenure of office began with the establishment of the Medical Association of South Africa as a group of Incorporated Branches within the British Medical Association. He played a great part in the steady growth and development of the Association he served. In retirement he saw on Dec 31, 1945, the final separation of the Branches in South Africa from the parent Association, and the first steps taken towards affiliation.

Major-General A J Orenstein writes. Although I first met Louis Leipoldt in 1918, it was during his tenure of office as Organizing Secretary of the Medical Association of South Africa and Editor of its journal, particularly during the seven years of my presidency of the Federal Council, that I got to know him well. He held both offices for about twenty years during which he contributed much to the growth of the association and the journal. In this time the association grew into a powerful and influential body, and the journal kept full pace with the growth of the association. Leipoldt was rather impatient of restraint and resentful of what he considered undue interference. Thus there were some clashes between him and certain members of the Federal Council. Towards the end of his incumbency his health was poor and he considered retirement several years before he finally left. By this time the association and the journal were firmly established.

His contributions to Afrikaans literature earned him most deservedly a very high place in the esteem of South Africans. To this others more competent than I have borne testimony. A gifted man and a notable personality has passed away.

Dr JOHN INGRAM of Devonport, died on March 4 at the age of 77. A student of Aberdeen, he qualified M.B., C.M. in 1893 and joined the Colonial Medical Service shortly afterwards. He was posted to West Africa and saw service in the Gold Coast hinterland, for which he was awarded the medal with clasp and bar.

Prof G Grey Turner writes. John Ingram, a Northern Scot, studied at Aberdeen in the days when Alexander Ogston was such an outstanding figure in surgery. His influence made a great impression on Ingram and, in consequence, from the outset of his career he was attracted to the surgical side of his work. After returning to this country from West Africa he started practice at Wallsend-on-Tyne where he came under the influence of, Rutherford Morison, whom he greatly admired. Ingram was quick to exercise his aptitude for surgery, and as most of his patients at that time were of the humbler class he frequently called me in and we did a great deal of operative work together. I am glad to acknowledge the value of those early experiences and have often stated that I learned my surgical work operating in the small industrial homes of Tyne-side at the invitation of John Ingram. The cases were of considerable variety, though most were abdominal emergencies. He was an excellent diagnostician and had a happy knack of managing his patients, who always seemed to be guided by his advice so that there was no delay in getting their consent for operative procedure. The houses usually consisted of only two or three rooms with perhaps a scullery. A neighbouring doctor gave the anaesthetic, which was always chloroform on an open mask. We operated on the kitchen table and scarcely ever had the luxury of a nurse and only occasionally the help of a 'handy body'. Of course the technique was of the simplest and was entirely on the antiseptic plan, but Ingram was a first-rate assistant and co-operated splendidly, and wound infection was almost unknown. In retrospect I now realize that the results were really most satisfactory. After some few happy years in this practice Ingram moved south, and for a time joined his cousin Peter, who had also migrated from Wallsend, in practice at Muswell Hill. Then after two or three years he went on to Devonport in 1908 where he continued in practice to the end. As age crept on there was a period a sort of interregnum when he took up bulb growing as a sideline and later he made several passages to the East mostly to China as a ship's doctor, but his real interest was always in surgery. During the 1914-18 war he was surgeon to the Military Hospital in Devonport and throughout the whole of this last war Ingram acted as medical officer at a transit camp in Devonshire. It was towards the end of his service there that he began to exhibit some evidence of failing health but fortunately he was spared the tedium of a long illness.

Apart from the absorption of his work and his family his main interest was in country life, and he loved to steal away,

without preparation or formality, to his beloved Aberdeenshire or to the border country for a few days with rod or gun. John Ingram was a man of quiet efficiency and determination with high ideals and a strict professional code, and with a lasting sense of gratitude to those whom he conceived had helped or influenced him. His calm, even temperament and good humour inspired confidence and engendered affection in hosts of patients who mourn his loss. He is survived by a widow, a son, who is also in the profession, and five daughters.

Dr ARTHUR JAMES LEWIS died in Southport on March 26. A student of Edinburgh University, he qualified in 1904, and proceeded M.D. two years later. He held resident posts in the Royal Infirmary and the Simpson Memorial Hospital, and spent some time in the mission field before settling in Southport, where at first he worked in close association with his brother. For many years he played an active part in the work of the British Medical Association. He was a member of the executive of the Southport Division for twelve years, and he also held the offices of secretary and chairman. For some years he was secretary of the local medical war committee and president of the Southport Medical Society. For twenty-five years he was secretary of the panel committee and for most of that time representative at the Panel Conference. This last outstanding service was acknowledged on his retirement, by the presentation of a written testimonial and a cheque from his colleagues. Dr Lewis was medical officer to the local branch of Dr Barnardo's Homes, and in the 1914-18 war he served in the R.A.M.C. During the recent war the loss of his son on active service took its toll, but so far as his strength permitted he continued his services to his patients and to the profession. Never obtruding though always ready to avow and support his opinions, Lewis was held in the affection and esteem of his colleagues, whose sympathy goes out to his widow and two daughters.

Medico-Legal

A LOST INDEX FINGER

[FROM OUR MEDICO LEGAL CORRESPONDENT]

A butcher's wife, of Doncaster, made a deep cut in the index finger of her right hand in September 1945. She went to the assistant of the two partners whose insured patient she was. Eventually the finger became gangrenous and she had it amputated by another doctor. She brought an action against the partners and the assistant, which was heard before Mr Justice Oliver at Leeds Assizes at the end of March¹. She said in evidence that on her first visit the doctor had washed the wound under a running tap and bound the finger with adhesive strapping. She complained of pain and at the second visit he had given her two morphine tablets, but she alleged that he did not examine the finger properly, he covered the old strapping with more tape, which he wound tightly. It was left in place at a third visit. At a fourth one of the partners removed it but applied another tight bandage.

The assistant said in evidence that he had wished to stop further loss of blood. He had told the patient that she would have to rest her hand and see him in two or three days. At the third visit he could see that the wound was still bleeding, and blood was showing through the dressing. He removed it sufficiently to see that blood was still flowing freely. He prescribed further rest. There was no obstruction to the circulation. A Sheffield surgeon said in evidence that great care should have been taken with the bandaging of the finger and that the strapping should not be so tight as to cause constriction.

In giving judgment Mr Justice Oliver said that he had not been favourably impressed by the assistant as a witness. His manner had been extremely nervous and uncertain. The patient's manner had been eloquent of truth, and he had no hesitation in preferring her evidence to the doctors. He had no doubt that gangrene had been set up by the constriction of the strapping. It had been the assistant's obvious duty to remove the first bandage and rebandage the finger. He awarded £350 general damages and £12 1s agreed special damages, with costs, against the assistant, with liberty to apply against the partners.

Universities and Colleges

UNIVERSITY OF LONDON

ST THOMAS'S HOSPITAL MEDICAL SCHOOL

Prof W G Barnard, FRCP, director of the Department of Pathology, has been elected Dean of St Thomas's Hospital Medical School in succession to the late Prof B A McSwiney.

The title of Professor Emeritus of Chinese Art and Archaeology in the University has been conferred on Walter Perceval Yetts, CBE, D Lit, MRCS, LRCP, on his retirement from the Chair of Chinese Art and Archaeology at the Courtauld Institute of Art.

The title of Reader in Physiology in the University has been conferred on Charles Cyril Norrey Vass, MSc, PhD, MB, ChB, in respect of the post held by him at St Thomas's Hospital Medical School, from Oct 1, 1946.

Sir Paul Fildes, MB, BChir, FRS, has been recognized as a teacher of biochemistry at the Lister Institute, in the Faculty of Science.

The following appointments have been approved for the purpose of the MD, Branch I examination: House physician, resident medical officer, and medical registrar at the Central Middlesex County Hospital, house physician, resident medical officer and medical registrar at the West Middlesex County Hospital, house physician, resident medical officer and medical registrar at the Redhill County Hospital, house physician at the Hillingdon County Hospital.

The following have been added to the list of areas approved for the purposes of instruction in public health administration for the DPH: Metropolitan Borough of Hammersmith, Metropolitan Borough of Islington, Municipal Borough of Wembley, Urban District of Harrow.

UNIVERSITY OF SHEFFIELD

At a Congregation to be held on July 1 the honorary degree of DSc will be conferred on Sir Howard Florey, MD, FRS, professor of pathology in the University of Oxford.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Prof Ronald Epey Lane, FRCP, will deliver the Milroy Lectures on Tuesday, May 20, and Thursday, May 22, at 5 p.m., at the College, Pall Mall East, SW. His subject is 'The Care of the Laid Worker'.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, with Prof G B Fleming, President, in the chair, the following were admitted Fellows of Faculty *qua* Physician: J Allan, MB, R T S Gunn, MB, J R Lauckner, MB, A C Macdonald, MB, J H Ramage, MB, D N Ross, MB.

The following were admitted Fellows of Faculty *qua* Surgeon: J A V Hamilton, MB, D J Livingstone, LRCP & SEd, I McLennan, MB, V Muhamed, MB, J Neilson, MB, A Paterson, MB, W Reid, MB, D G Smith, MB.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The William Blair Bell Memorial Lecture on 'Tubal Occlusion' will be delivered by Mr Linton M Sneath, MS, FRCS, at the College (58, Queen Anne Street, London W) on Wednesday, May 14, at 5 p.m. The William Meredith Fletcher Shaw Memorial Lecture will be delivered by Prof F J Browne, M.D., FRCSEd, at the College on Friday, July 4, at 3 p.m. His subject is 'Hypertension in Pregnancy', at 5 p.m., Mr J A Stallworthy will deliver the Biennial Scholarship (Sterility) Lecture on 'Fact and Fantasy in the Study of Female Sterility'. All members of the medical profession are invited to attend the lectures but admission is by ticket only obtainable from the secretary. Applicants should indicate for which lectures tickets are required.

SOCIETY OF APOTHECARIES OF LONDON

On May 8 the Honorary Freedom of the Society will be conferred upon Sir Stanley Hewett, Surgeon Apothecary to the King, and the Honorary Mastery of Midwifery will be bestowed upon Sir Allen Dray, Sir Eardley Holland, and Sir William Fletcher Shaw. The time of the ceremony is 8 p.m. for 8.30 p.m., a *soirée* will follow.

COLLEGE OF PHYSICIANS AND SURGEONS OF BOMBAY

The Council of the College of Physicians and Surgeons of Bombay at its meeting held in January decided to institute postgraduate diplomas in the following subjects: (1) dermatology and venereology, (2) otorhinolaryngology, (3) orthopaedics, (4) anaesthetics, (5) radiotherapy, (6) anatomy, and (7) physiology. The regulations relating to the examinations for these diplomas are in course of preparation.

Medical Notes in Parliament

THE BUDGET

On Tuesday, April 15, Mr DALTON the Chancellor of the Exchequer, in his Budget statement said that he was providing this year £25,000,000 more for housing and for the preliminary expenses of the national health services. There was also £23,000,000 more for the Ministry of National Insurance. Family allowances had cost this year £4,000,000 more than had been expected. He had been told that there were some 200,000 more eligible babies than were allowed for by the actuaries. Many uncertain factors would affect next year's Budget. They would see, however, increases in the expenditure on social services. In particular there would be an increase in the national expenditure on health following the transfer of the hospitals from local to national ownership. Next year the Minister of Health and the Secretary of State for Scotland would help him to rearrange the relationships of national to local finance at a cost to the Treasury of a little less money. A new block grant was needed, better arranged and costing less, and, so far as its distribution among local authorities was concerned, acting to a greater extent than heretofore for the benefit of the poorer authorities.

In his concluding remarks on the revision of the tobacco duty, Mr Dalton said, 'All we need to do is smoke a little slower. We must throw away our stubs a little shorter and knock out our pipes a little later. All this may even be quite good for our health and the state of our nerves.'

Scottish Health Services

The National Health Services (Scotland) Bill was considered in Committee in the House of Commons on Monday, April 21.

Mr WESTWOOD, on Clause 22, moved an amendment to delete the section appointing the local health authority as the local authority for the purposes of Part I of the 1937 Children and Young Persons (Scotland) Act. He said that since the Bill had been drafted the Clyde report on the care of homeless children had been received and was being considered. The amendment was agreed to the Committee stage was concluded and the motion for the Third Reading was debated.

Mr WALTER ELLIOTT moved an amendment for the rejection of the Bill on the grounds that it centralized control of institutions in the hands of the Secretary of State, deprived local authorities of the powers of administration, took power to divert trust funds against the wishes of the donors, and gravely threatened the future practice of medicine in the wider sense. After a full debate the amendment was defeated by 143 votes to 54, and the Bill was read a third time.

(A full report of the debate has had to be held over till our next issue.)

Mass Radiography.—On April 17 Mr CALLAGHAN asked when Mr Bevan expected to extend to all school children the benefit of the mobile x-ray units for detecting chest troubles at an early stage. Mr BEVAN said mass radiography was steadily increasing and would be extended to more children as apparatus and staff became available. Present experience suggested that it was of more value at school leaving age than before.

The Services

CASUALTIES IN THE MEDICAL SERVICES

Killed in Action.—War Subs active Captain John Wayne Gordon RAMC.

INDIAN MEDICAL SERVICE DINNER CLUB

The Indian Medical Service annual dinner will be held at the Connaught Rooms, Great Queen Street, Kingsway, London WC on Thursday, June 12, at 7 p.m. for 7.30 p.m., when Lieut Gen S Bennett Hance will preside. The cost of the dinner is £2 2s per head, inclusive of wines, cigarettes, and gratuities to waiters. The charge for a ticket to those members of the Dinner Club whose subscription is not in arrear will be 16s 6d, while the charge in all other cases is that charged by the caterers, viz., £2 2s. Dress will be either dinner jacket, dark lounge suit, or service dress, but decorations will not be worn with civilian attire. Emergency commissioned officers, including ladies, are invited to attend, and are also eligible to become members of the club. Applications to attend the dinner should be sent, together with a remittance, to Mr A W Brown of Grindlays Bank, Ltd (54 Parliament Street, London, SW 1).

‡ In latest puerperal fever for England and Wales and Eire

Return of births and deaths for Eire from week ended March 8 to week ended April 5 appears on page 584

EPIDEMIOLOGICAL NOTES

Influenza in Europe

During the winter of 1946-7 the incidence of influenza varied from near epidemic to virtual absence in European countries. The largest outbreak recorded was that in Sweden, where 25,000 cases occurred in the central and southern section of the country during the first five weeks of this year. The epidemic was due to a benign type of virus A and the mortality was insignificant. The neighbouring north-western countries recorded no undue prevalence of influenza. The only other countries with a high incidence were Belgium and Bulgaria. In Belgium 10 to 15% of the population suffered a mild attack in January and February, and in Bulgaria the incidence rose sharply in February but only a few deaths were recorded. In most of the countries for which information is available the distribution of the disease was patchy and of low virulence. In those countries where the virus has been isolated an A type was found. In England and Wales the virus A isolated this winter was antigenically somewhat different from that recovered in previous outbreaks.

Sanitary Control of Ice cream

New regulations for the heat treatment of ice cream will come into force on May 1. They are regulations made by the Ministry of Health under the Food and Drugs Act, 1938, and originally put forward in the form of a Draft Order which was the subject of an annotation in the *Journal* of Oct 19, 1946 (p 584). Ice cream prepared by typhoid carriers was responsible for outbreaks of typhoid fever at Aberystwyth and at Coatbridge, Lanarkshire, last year, and for less spectacular outbreaks in other parts of the country. It will be recalled that at Aberystwyth Vi-phage Type C organisms from a urinary carrier who was an ice cream merchant gave rise to 210 cases with 4 deaths.

The new 'Ice cream (Heat Treatment, etc.) Regulations, 1947' will mean that, in effect, the mixture of which ice-cream is composed must be pasteurized before freezing. It may be heated either to 150 F (65.5°C) for 30 minutes or to 160 F (71.1°C) for 10 minutes. Further regulations govern the subsequent cooling process and the maintenance of a sufficiently low temperature thereafter. These requirements do not apply when a "complete cold mix powder" is used, supplied in air-tight containers and manufactured from previously heat-treated material. This may be made up with 'wholesome drinking-water,' and colouring or flavouring materials, fruits, nuts, or chocolate may be added without subsequent pasteurization. The apparatus used must be installed, maintained, and operated to the satisfaction of the local authority, and a general requirement has been made to the effect that ice cream, during its manufacture, storage, and distribution, shall at all times be protected from contamination, and also that all apparatus and utensils brought into contact with it shall be cleansed immediately after use and kept clean at all times. The Minister has given further consideration to the prescription in the Regulations of a bacteriological standard of cleanliness for ice-cream, but he is still not satisfied that there is any test the reliability of which is sufficiently established to justify its use as a statutory test, non-compliance with which would constitute an offence. Attention is drawn, however, to a form of methylene blue test, adapted for testing ice cream, particulars of which were published in the Ministry of Health's *Monthly Bulletin* for March, 1947.

Outbreaks of Smallpox

Up to April 22 no further outbreaks had been reported. The foci at Grimsby, Stepney, and Doncaster are believed to be extinct, following control by surveillance and vaccination of close contacts.

At Scunthorpe the number of confirmed cases remains 7. The last case was removed on April 12 (onset April 7, rash April 12).

At Bilston the position is unchanged. The last of the 8 patients died at home in the prodromal stage on April 11. The last removals to hospital were on April 10.

Decennial Supplement Part IV

The Registrar General's *Decennial Supplement*, 1931, Part IV, Multiple or Secondary Causes of Death, has just been published. This volume was prepared before the war to meet the need for knowledge in mortality studies of the secondary causes of death. A sampling method was employed in the preparation of this volume, because of the large numbers of deaths involved. A proportion of the deaths classified in each International List heading was studied, such proportion varying inversely according to the total numbers assigned to the heading and ranging from the whole in the case of small numbers to one tenth in the case of the largest. Each group was not

sampled in the same year but relates to one of the years during 1923-30. All the figures are based on the classification of causes of death in use in 1921-30. Any comparison with figures from a later period will be affected by the revision of the classification which has been made. This will be so particularly for years after 1940 when the certifying practitioner's preference was adopted in place of a given rule of selection.

Infectious Diseases during the First Quarter

A summary of the weekly returns for England and Wales for the first thirteen weeks of this year shows that the incidence of infectious diseases has been relatively light. Diphtheria was at the lowest level ever recorded and at less than half the level of the two preceding first quarters. A dramatic fall has occurred in the returns for dysentery although some of this may be more apparent than real. The diseases which were slightly more prevalent were whooping cough and cerebrospinal fever.

Returns for the First Quarter of Each of the Last Five Years

England and Wales	1943	1944	1945	1946	1947
Scarlet fever	26 759	26 962	19 163	16 952	15 527
Whooping-cough	23 005	26 141	19 780	20 033	27 922
Diphtheria	10 799	9 005	6 061	6 220	2 832
Measles	220 556	20 278	247 455	17 652	165 895
Acute pneumonia	18 211	14 977	14 782	16 278	15 500
Cerebrospinal fever	1 287	978	968	906	1 110
Dysentery	1 317	2 834	4 681	4 444	931
Paratyphoid and typhoid	175	111	140	138	98
Deaths from influenza	1 149	1 131	692	2 156	1 342
Case mortality per 1 000					
Scarlet fever	1.9	1.2	1.7	1.2	1.2
Whooping cough	14	11	16	10	14
Diphtheria	47	34	29	31	26
Measles	2.6	1.3	1.9	3.5	2.4
Live births	83 801	90 109	87 123	97 468	132 825
Infant mortality	67	62	68	60	58

Deaths from influenza were in excess of those for some recent years, but were less than half the number in the first quarter of 1940 and less than one fifth of those in the same quarter of 1937. The fatality rate from diphtheria fell to the lowest level of recent first quarters. The live births were 36% above the number recorded in the March quarter of last year. Infant mortality was below that of the preceding first quarters.

Figures for Eire

The table below gives the returns for the principal towns of Eire for the last five weeks for which figures are available. During this period there were no deaths due to diphtheria, dysentery, scarlet fever, smallpox, typhoid or typhus.

Week ending	Deaths under 1 year	Birth Rate	Death Rate	Causes of Death			
				Diarrhoea and Enteritis (under 2 yrs)	Measles	Influenza	Whooping cough
March 8	64	31.1	26.2	16	2	10	3
15	76	29.2	25.6	11	—	3	9
22	55	22.0	23.3	11	2	4	5
29	63	24.5	22.1	8	—	6	9
April 5	62	23.4	17.9	10	—	2	9

Discussion of Table

In England and Wales infectious diseases were less prevalent during the week and large falls were recorded in the incidence of measles 2 437, whooping cough 488, scarlet fever 322, acute pneumonia 295, diphtheria 70, dysentery 41, and cerebrospinal fever 29.

The fall in the notifications of measles was general except in the eastern counties, where a rise of 92 was recorded. The incidence of whooping cough remained unchanged in the eastern and north midland counties, while declining elsewhere. A fall in the number of cases of scarlet fever occurred in all areas except Wales where a small increase was reported.

The largest decrease in the incidence of acute pneumonia was in the south-west region, where the notifications fell from 71 to 16. The only variations of any size in the local trends of diphtheria were decreases in Lancashire 28 and London 10. The experience of Lancashire was mainly due to the county boroughs. Lancashire 16 was the only important centre of dysentery and 10 of these cases were notified from rural areas.

In Scotland there was a considerable fall in the notifications of infectious diseases. The decreases included whooping cough 160, acute primary pneumonia 144, measles 116, scarlet fever 65 and cerebrospinal fever 12.

In Eire a decline in the incidence of infectious diseases was reported. The largest falls were in the notifications of whooping cough 23, diarrhoea and enteritis 16 and measles 11.

In Northern Ireland falls were recorded in the notifications of scarlet fever 24, whooping cough 14 and diphtheria 8. An outbreak of measles involving 12 persons was reported from Lisburn UD.

Week Ending April 12

The notifications of infectious diseases in England and Wales during the week included scarlet fever 928, whooping cough 1,751, diphtheria 213, measles 10 326, acute pneumonia 709, cerebrospinal fever 89, dysentery 77, smallpox 13, acute poliomyelitis 11, paratyphoid 1, typhoid 6.

Medical News

The St Bartholomew's Hospital Cricket Club will hold its first post-war annual ball at Grosvenor House Park Lane, London, W, on Saturday, May 3, from 8 p.m. till 1 a.m. Music by the Blu Rackets Dance Orchestra. Double tickets (2½ guineas) are available from the honorary secretary, St Bartholomew's Hospital Cricket Club, London, E.C.1.

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, Cavendish Square, London, W, to-day (Saturday, April 26), at 2.30 p.m., when Sir Weldon Dalrymple Champneys will read a paper on 'The Epidemiological Control of Venereal Disease'.

The annual general meeting of the Central Council for the Care of Cripples will be held at Cowdray Hall, 1a, Henrietta Place, Cavendish Square, London, W, on Thursday, May 1, at 2.30 p.m., when the Minister of Education, the Rt. Hon. George Tomlinson M.P., will address the meeting.

The Société Suisse de Médecine Interne will hold its annual meeting at Rheinfelden on May 3-4. Prof. H. Staub of Basle, will give a clinical demonstration, and Profs. L. Brull of Liege, A. Fleisch of Lausanne, and E. Uehlinger, of St. Gall, will lecture on various aspects of nutrition and starvation.

A clinical meeting of the Irish Tuberculosis Society will be held at the Royal College of Surgeons in Ireland, Dublin, on Friday, May 2, at 7.30 p.m., when the speakers will be Dr. G. S. Todd, 'Collapse Therapy—Its Uses, Complications and Contra-indications'; Dr. Wm. MacPhail, 'Rehabilitation in Relation to Tuberculosis'; Dr. Morgan Crowe, 'Dispensary Organization in Tuberculosis'; and Mr. F. J. Henry, 'Surgery in the Treatment of Pulmonary Tuberculosis'. Members wishing to attend should notify the honorary secretary of the Society, The Hospital, Newcastle, Co. Wick. Membership is open to all registered medical practitioners. Annual subscription, 10s. 6d.

The North West Area Association of Scientific Workers is holding a conference on 'Industrial Health' to-day (April 26), at 2.45 p.m., at Milton Hall, Deansgate, Manchester. Prof. R. E. Lane of the Department of Industrial Health, the University of Manchester, is delivering an address entitled 'Production Comes from People'.

A Paediatric Congress will be held under the auspices of the Congrès des Pédiatres de Langue Française on May 22-24, 1947, at Lyons. The following subjects will be discussed: chronic rheumatism in childhood; malignant neoplasms in childhood; the treatment of acute meningitis in childhood. Further information may be obtained from the general secretary, Dr. M. Jeune, 24, Place Bellecour, Lyon, France.

Mr. D. D. Stenhouse Stewart, D.O.M.S., and Mr. J. Lumsden M.A., of the Ministry of Education, will open a discussion on 'The Education of Blind and Partially Sighted Children' at a meeting of the School Medical Service Group of the Society of Medical Officers of Health to be held in the Civic Hall, Leeds, on Wednesday, April 30, at 2.20 p.m. The meeting has been arranged at the request of the Minister of Education's Advisory Committee on Handicapped Children.

A clinical pathological demonstration of haemochromatosis will be given in the Meyerstein Lecture Theatre of Westminster Hospital School of Medicine (Horseferry Road, S.W.) on Monday, May 5, at 5 p.m.

On May 5 the out-patient department of the Central Branch of the Moorfields Westminster and Central Eye Hospital will be transferred to the Westminster Branch (Royal Westminster Ophthalmic Hospital), High Holborn, London, W.C. Medical practitioners are asked to make a note of this change so as to prevent patients attending Judd Street when they should go direct to High Holborn. The out-patient times at the Westminster Branch will be the same as those at the Central Branch and any further information can be obtained from the Westminster Branch (Tel. Temple Bar 1457).

PHENOXYETOL

P. E. E. G.

THE ANTI-PYOCYANEA COMPOUND

HERE is an important new bactericide and antiseptic. Phenoxetol (Nipa) is B phenoxethyl alcohol specially purified and standardised for use in medical treatment and for pharmaceutical preparations.

Phenoxetol is effective against certain gram negative organisms including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds, abscesses, indolent ulcers associated with *Ps. pyocyanea*. It should not be used for parenteral injections.

Phenoxetol is very effective in pyocyanea infections of burns or superficial wounds. It is especially useful in the preparations of surfaces for skin grafting associated with *Ps. pyocyanea* and may also be used together with Penicillin in solutions and creams.

NEW PLASTIC SURGICAL DRESSING

replaces bandages

PRIMARILY intended for fixing surgical prostheses to the skin, surgeons soon found other uses for Portex Plastic Skin.

In Blood Transfusion—to replace bandages and dressings

As a Surgical Barrier—tested as a germicidal preoperative barrier, results exceeded all expectations. It was remarked that excoriating fistulae never supervened during operations in which they had been too common.

After this operation a further application effectively seals the wound and prevents excoriation of the skin by digestive ferments, which escape to the surface via the drainage tubes, etc., particularly following gall-bladder and gastric operations.

General Uses—Portex Plastic Skin is a handy and effective treatment for cuts and abrasions, small burns, mosquito and other insect bites, pruritus, cracked nipples during lactation. Free samples and literature from the manufacturers: Portland Plastics Limited, 6, Victoria Street, London S.W.1.

"PORTEX" PLASTIC SKIN

Formula: Phenyl Salicylate, Methyl Methacrylate, etc.
Resin, etc. u. Lignol, etc. Chloroform, etc. Volatile Solvents, etc.

In tubes and in 25 cc, 56 cc, 156 and 600 c.c. bottles

RATIONAL THERAPY IN BUCCO-PHARYNGEAL INFECTIONS

The Twenty-Lozenge Pack

Penicillin Lozenges A & H are issued in glass tubes to prevent inactivation of the penicillin by atmospheric moisture.

The number of lozenges contained in the tube (TWENTY) provides the most suitable package to meet the needs of individual treatment prescribed by the physician. Not only does it tend to eliminate waste but it assures the prescriber that the lozenges will not have time to become inactivated by exposure to a moist atmosphere before the prescribed treatment is completed.

Penicillin Lozenges A & H are indicated for the effective local treatment of bucco-pharyngeal infections.

In tubes of 20 Lozenges

PENICILLIN LOZENGES A & H

ALLEN & HANBURYS LTD, LONDON E 2

for— Skin Infections

Defective nutrition is one of the factors predisposing to skin infections and more than one vitamin is concerned in maintaining a healthy condition of the skin. As a preliminary in the treatment of skin diseases the dietary regime should be revised in order to be sure that the intake of vitamins is adequate.

While some cases show improvement after administration of one member of the vitamin B₂ group others derive no benefit unless the whole complex is given. Marmite is therefore particularly useful in these conditions as it contains all the better known vitamins of the B₂ complex as well as other factors the specific actions of which are less accurately known.

MARMITE

yeast extract

contains

Riboflavin (vitamin B₂) 15 mg per oz
Niacin (nicotinic acid) 16.5 mg per oz

Jars 1 oz. 8d 2 oz. 1/1 4-oz. 2/ 8-oz. 3/3 16 oz. 5/9

DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

indicated in

**Cardiac Decompensation, Oedema,
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Deriphyllin-Strophanthin is indicated for all cases of heart failure.

Available in liquid form for oral use
ampoules and suppositories

Literature and samples on request

a sure and simple

analgesic ointment

Anethaine Ointment is a powerful local anaesthetic with the very special quality of exerting a direct effect on the skin or mucous membrane. It is effective within a few minutes of application and maintains full analgesia for two hours or more. Many uses for Anethaine Ointment are apparent in everyday practice. For instance as a lubricant in instrumental examinations to render them painless and for the relief of local pain and discomfort which accompany many affections such as haemorrhoids fissure a small burn or sting. Other conditions where the ointment may be used to advantage will suggest themselves.

Anethaine Ointment contains 10 per cent of the fat soluble base of amethocaine hydrochloride. It is non greasy and easily removed with water from skin or clothing.

Vitamin Therapy — its uses and limitations

NERVOUS DISORDERS

Clear evidence is available that several dietary factors influence the structure and function both of the peripheral nerves and of the nervous tissue of the brain and spinal cord, and there are indications as to the value of Bemax in the treatment of some types of neuropathy. In cases showing early signs of functional or of degenerative nervous disease, the regular use of Bemax may assist the disappearance of biochemical lesions.

Bemax is already in wide use as a means of preventing relapse in cases in which deficiency neuritis has been cleared up by intensive vitamin B₁ therapy. It is recommended also for cases of hypertrophic muscular dystrophy.

BEMAX Stabilised cereal embryo

1 oz. of Bemax provides approximately —

Vitamin B ₁	0.45 mg	Vitamin E	8.0 mg	Available

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Termination of Pregnancy on Genetic Grounds

Q—In what heredo-familial disorders should advice be given against future pregnancy or for the termination of an existing pregnancy?

A—Surely the duty of a medical man is not simply to advise against future pregnancy on genetic grounds, or alternatively to advise abortion, but rather to explain to the patient what the chances are, and apart from this to offer no more than such guidance as may be directly requested. The responsibility for a decision must lie chiefly with the patient. Furthermore, it will depend on more than the genetic odds. For example, a young couple who have lost their two babies soon after birth owing to some recessive defect, when informed that the chance of losing the next one in the same way is one in four, may courageously decide to run that risk. Another couple, however, with the same history may say that they dare not face the prospect, that they will give up all thought of having another child of their own and will adopt one instead. Or, in another instance, the doctor may agree that the mental strain of another pregnancy with its one-in-four risk constitutes a serious threat to the mother's mental health.

There exist many hundreds of human hereditary abnormalities, nearly all of course, being individually rare though not numerically unimportant in the aggregate. Transmission is not always simple and not always the same. The individual family history must be investigated and then interpreted in the light of the literature. The chances, when they are known or can be deduced, should then be explained to the couple, whose decision cannot but be affected by their attitude to parenthood and children, their religious beliefs, and their age and by the numbers and kind of children they already have.

Sebaceous Cysts

Q—A young man has had four sebaceous cysts removed from his face during the past three years and more are beginning to form. Is any preventive treatment possible?

A—Sebaceous cysts may arise as retention cysts from blocking of the pilo-sebaceous orifice as in acne. Apart from this group the majority of these cysts are naevoid in origin and the condition is often familial. There is no preventive treatment.

Treatment of Post-herpetic Pain

Q—What is the best treatment for severe and long-standing post-herpetic pain?

A—Treatment of post-herpetic neuralgia is often unsuccessful. The possibility of a psychoneurotic background must not be overlooked. Measures which sometimes give relief are iodides, vitamin B in large dosage, cannabis indica, and x-ray therapy to the appropriate ganglion area (400 r units at 90 kV through 2 mm aluminium). Short-wave diathermy and ultra-violet light locally have sometimes helped.

Non union after Arthrodesis

Q—What are the causes of repeated failure of full bony union in an arthrodesis of the knee carried out between the ages of 38 and 45?

A—It is impossible to answer this question as comprehensively as one would like without at least a series of radiographs and without knowing the type of fusion performed. It should nowadays be possible to secure fusion without fail in the very large majority of patients between the ages of 38 and 45. Below is a list of the possible causes of failure of bony union in such a case.

General Causes—Any general disease which has lowered the patient's vitality to a stage where osteogenesis is not active—for example various vitamin deficiencies or any disease which has resulted in sclerotic changes in bone such as syphilis.

Local Causes—(1) The condition for which fusion of the knee is desirable—for example, union is slower or less likely to be complete in an arthrodesis for a tuberculous lesion than in one for injury or rheumatoid arthritis. (2) Imperfect operative technique. (a) Failure to expose raw cancellous bone in the opposing surfaces of the tibia and the femur. (b) Failure to obtain close end-to-end contact. It is wise to pack the "nooks and crannies" with bone chips taken from the ilium. (c) Failure to secure complete fixation. Probably the best method of doing this is to use crossed tibial grafts—the method described by Brittain. This procedure alone increased the rate of success in fusions for tuberculosis from about 66% to over 90%. There are, of course, other methods of fixation, such as an obliquely placed Smith-Petersen nail. External splinting by a plaster-of-Paris spica is also necessary.

Finally, anomalies of blood supply, whereby the end of one bone may be ineffectively supplied (an almost theoretical consideration), should be included in a list of causative factors.

Dyspareunia after Hysterectomy

Q—What treatment might be applied in a case of dyspareunia after panhysterectomy? As the normal cervical secretions are removed is there any effective lubricating ointment or any hormone treatment which might prevent the menopausal atrophy of the vagina?

A—The cervix does not normally play the dominant part in lubricating the vagina during coitus. The secretion comes mainly from Bartholin's glands and is poured out as a result of sexual stimulation. Even so, if both ovaries were removed at the time of the hysterectomy the activity of Bartholin's gland is likely to have decreased if not ceased. Menopausal atrophy of the vagina can be overcome by oestrogens. A large dose may be required, and in the first place hexoestrol, 1 mg thrice daily by mouth for three weeks, should be tried. After an interval of two weeks this course could be repeated. It should not, however, be continued for longer than that, and should in any case be stopped as soon as coitus is possible again. When it is discontinued the vaginal epithelium will atrophy again, but the vaginal canal should not undergo contracture if it is kept dilated by regular coitus. If for any reason coitus is discontinued for an appreciable time contracture will recur. If necessary an artificial lubricant can be employed, and the preparations used for the passage of catheters are suitable for this purpose.

Loa loa Infection

Q—What is known regarding the persistence of *Loa loa* in the human body? Is there any satisfactory treatment for Calabar swellings?

A—Symptoms of loasis may first become apparent some years after the patient has left an endemic area, and may continue for ten to fifteen or more years. Treatment consists in removing such adult worms as may present themselves in convenient situations for extraction, but the infection is usually multiple and symptoms may continue. Local manifestation may require symptomatic treatment, while allergic reactions may be diminished by such drugs as phenobarbitone, benadryl, or ephedrine. Desensitization by increasing doses of filarial antigen has also given promise experimentally. There is some evidence that certain antimony compounds may be useful in filariasis, but, as their effect is probably on the adult worms, microfilariae may persist in the peripheral blood for many months after treatment. Phenomena due to sensitization to filarial products may also persist for some time after treatment.

Sodium Bismuthyl Tartrate in Rheumatoid Arthritis

Q—Is sodium bismuthyl tartrate of value in the treatment of infective and rheumatoid arthritis? What is the dosage, at what intervals and for how long a period is it given and what are the toxic effects?

A—Sodium bismuthyl tartrate has not been in use long enough to enable a definite opinion to be formed as to its value in the treatment of arthritis of the rheumatoid type. It would appear to be less effective than gold, but useful where gold is not tolerated or where it has ceased to produce any improvement. The writer has used it in a good many cases with variable results, but with undoubted improvement in a

few, no toxic effects have been observed beyond some sense of malaise and fatigue for a day or two after administration. It is given by deep intramuscular injection, and this sometimes gives rise to pain at the site of injection. It is injected at fortnightly intervals in a solution of 1 gr (65 mg) in 1 ml, the dose to begin with being 0.5 ml; this may be increased up to 1 ml and the interval then may be a month, after six or eight doses an interval of a few months is desirable.

Pressure Cooking

Q—When food is cooked at 20 lb (9 kg) positive pressure and at a temperature up to 250° F (121° C) is there any loss of food value compared with ordinary cooking and does it incur a greater risk of food poisoning especially from meat?

A—Little work seems to have been done with domestic pressure cookers but, generally speaking, the effects may be expected to be similar to those of commercial canning. As compared with ordinary cooking, some further destruction of vitamin B₁ (thiamine) may occur, owing to the higher temperature reached. Loss of vitamin C may or may not be greater than with ordinary cooking, since although the conditions are more drastic, the time of exposure is less. Meat and vegetable juice may be more abundant and should not be thrown away.

We have found no reference suggesting any danger of food poisoning resulting from the use of a pressure cooker. This idea may have arisen from the fact that meat cooked in this way may develop a bitter flavour. This has been ascribed to the partial breakdown of some of the proteins into simple peptides and amino acids. On the other hand, the use of a pressure cooker in the home canning of vegetables obviates the risk of bacterial poisoning.

Pruritus Senilis

Q—What is the best treatment for pruritus senilis and is a cure likely?

A—There are many possible activating factors in senile pruritus particularly emotional and nervous stresses and strains, metabolic disturbances and deficiency states. Glucosuria, hypertension, arteriosclerosis and neoplasms must be carefully considered. In essential senile pruritus the senility of the skin itself may play some part, but the condition seems more often dependent upon arteriosclerotic changes affecting the central nervous system, and treatment is difficult. Local applications are not of much avail, though minimal doses of ultra-violet light or x rays are sometimes of value. Stilboestrol 0.5 to 1 mg combined with phenobarbitone gr 1/2 (32 mg) occasionally helps.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Postgraduate Education for Ex Service Medical Officers

A note on this subject appeared in the *Journal* of Jan 18 (p 124). We have now been informed by the Ministry of Health that the Minister has been in communication with the Board of Inland Revenue regarding the liability for income tax of doctors holding posts or taking courses under the Postgraduate Scheme. He is advised that, as the practitioners holding Class I and Class III posts are employees of the hospitals to which they are appointed the salaries of these posts and the allowances of £100 paid in lieu of board and lodging are assessable to income tax under Schedule E, and tax should be deducted by the employing hospital under the PAYE provisions on making payments on account of these salaries and allowances.

The practitioners attending refresher courses provided under Class II will, in general, be liable to income tax under Schedule D upon the profits of their individual practices. Payments made to a practitioner in respect of subsistence travelling expenses, and the cost of providing a locum are not in themselves income liable to tax. If, however, a practitioner in arriving at the amount of his practice profits deducts the corresponding expenses incurred by him then the payments received by way of reimbursement must be credited. For example a doctor who uses his practice car to attend lectures and charges the full car expenses in his accounts should credit the amount received from the Ministry in respect of journeys to and from lectures. Similarly, if the cost of providing a locum is debited in the accounts the amount reimbursed by the Ministry should be credited.

Letters and Notes

Bleeding Tooth sockets

Dr J F MURPHY (Pickering, Yorks) writes: Troubles from a bleeding tooth socket were ended for me by a method shown me by a neighbour dentist many years ago. It is extremely simple, painless, and instantly effective. One assumes of course that the gum is not so badly torn as to require a stitch. Two wool swabs of suitable size are prepared, one dry and one damp enough to coat itself thickly with crystals of permanganate of potash when dipped into the jar. The dry swab is pressed into the socket to check the bleeding as much as possible, and on withdrawal the swab coated with the crystals is pressed up into the socket and held there for about 30 seconds before withdrawal. A firm black adherent coagulum instantly forms and the bleeding is at an end. (No swab is left in.) Occasionally a further application of the crystals is required but not often. The coagulum disappears without trouble in the course of two or three days. For many years I have not known this method fail.

Multihallucism

Dr ROYAN O RAHILLY (Newcastle upon-Tyne) writes: With reference to the photograph of Dr Ardesir K. Turner's case showing a Hindu with two big toes on each foot (March 29, p 436) I should like to call attention to the skiagram (reproduced) which I possess through the kindness of Dr T Lodge FFR. It shows a very rare condition of three big toes on one foot, making a total of seven digits on the right lower limb. The patient was a boy who was aged six months when the film was taken. The thickened first metatarsal can be seen to be associated with three biphalangal digits. The remaining toes were normal. Other cases of pedal heptadactylism have been described (e.g., by Pires de Lima, J A, *Ann Anat Path med chir* 1933 10 1215) and a case of octodactylism has been recorded by A E Sawday (*British Medical Journal* 1928, 1 846). Most instances of pedal polydactylism, however, are concerned with the lateral border of the foot in contrast with the pre-axial distribution in the case illustrated here, as also in that of Dr Turner.

Chilblains

Dr MARGARET VIVIAN (Bournemouth) writes: The woman doctor (March 1 issue) crippled with chilblains should try calciferol and parathyroid and calcium tablets. I have cured my own by taking both these remedies together, when neither singly was completely successful.

Treatment of Dipsomania

Dr H PULLAR STRECKER (Truro) writes: The reply (March 15, p 365) and the references quoted refer to the American method, which is rather involved, emetine, not apomorphine, is their nauseating agent. The apomorphine method was evolved by J Y Dent and is described in the issues of the *British Journal of Inebriety* from 1934 onwards.

Correction

A correspondent points out that the Cerebral Palsy Unit at Carshalton referred to in our annotation (April 5, p 459) was founded by the cerebral palsy therapist 4 years ago with the backing of the LCC.

PRELIMINARY

Membership of the Association

1 The membership of the Association continues to show a very satisfactory increase. During the year 1946 there was a net increase of 2,667 and on March 31, 1947 the membership was 55,049.

A survey of the membership recently made by the Council shows that of the practising members of the profession in the United Kingdom over 75% are members of the Association.

Deaths

2 The Council regrets to record the deaths of 472 members during the year 1946.

Annual Meeting

3 Owing to the war no Annual Meeting with Scientific Sections has been held since the Association met in Aberdeen in 1939. The Council feels that as soon as possible the ordinary Annual Meetings of the Association should be resumed. It has accordingly accepted with pleasure the invitation of the Cambridge and Huntingdon Branch to hold the Annual Meeting for 1948 in Cambridge.

President of the Association

The Council recommends

Recommendation That Sir Hugh Lett Bart CBE DCL FRCS be re-elected President of the Association for the year 1947-8.

The Cambridge and Huntingdon Branch has nominated Sir Lionel Whitby as President for the year 1948-9. The Council recommends

Recommendation That Sir Lionel Whitby, CVO MC MA MD FRCP Regius Professor of Physic University of Cambridge be elected President of the Association for the year 1948-9.

Annual Representative Meeting

5 The Annual Representative Meeting will be held on Tuesday, July 22, 1947, at 2 p.m. It will continue on Wednesday and Thursday July 23 and 24, and, if necessary on the following day.

Vice-Presidents of the Association

6 Recommendation That J C Matthews MC MA MD FRCP, and H W Pooler, MB BCh, be elected Vice-Presidents of the Association as an appreciation of the exceptional services they have rendered to the Association.

The Secretariat

7 The Council has appointed Dr J H Bruce and Lieut Col J Revans IMS, as Assistant Secretaries of the Association.

Agreement between the Association and the Association of Industrial Medical Officers

8 The Council has entered into the following agreement with the Association of Industrial Medical Officers

1 If the Association of Industrial Medical Officers desires to urge upon central or local authorities, or other similar bodies, any medico-political policy affecting the interests of public or private practice, or is consulted thereon by such authorities or bodies it shall communicate its proposals to the British Medical Association before taking action.

2 If such policy or proposals are approved by the British Medical Association either in their original form or in an agreed amended form, all action consequent thereon will be taken by the British Medical Association, and the Association of Industrial Medical Officers will refrain from taking any further action.

3 If the proposals of the Association of Industrial Medical Officers are not approved by the Council of the British Medical Association, or if the former Association is dissatisfied with the form in which the Council of the British Medical

willing to take action thereon, the Association of Industrial Medical Officers shall be free to take action independently.

4 The British Medical Association will provide for the representation of the Association of Industrial Medical Officers on its Industrial Medicine Committee and the Association of Industrial Medical Officers will provide for the representation of the British Medical Association at its meetings.

Priority Supplies of Milk to Invalids

9 In November 1946 the Minister of Food published a statement (see *BMJ* Nov 2, 1946 p 661) drawing attention to the increasing demands by invalids on milk supplies. He attributed the increase to lax or improper certification by medical practitioners and announced without consultation with the profession the measures he was taking to reduce demands for priority supplies for sick persons. The Council strongly protested to the Minister against the issue of such a statement unsupported by evidence and against his failure to consult the Association as his predecessors had done in connexion with this priority scheme since 1941. It also informed him that it would be glad to confer with him on the general arrangements of the scheme and on measures which might be taken to deal with the particular situation which had arisen.

Ex-Service Practitioners

10 The Council made representations to the Ministry of Health

(a) That the number of Class I hospital posts under the Government's postgraduate scheme should be increased to enable ex-Service practitioners eligible for such posts to obtain them at a reasonably early date subsequent to their release from the Forces.

(b) That a greater number of Class III hospital posts be authorized both in teaching and non teaching hospitals to expedite the absorption of ex-Service practitioners eligible for such appointments under the Government's postgraduate scheme.

(c) That the present restriction whereby only those ex-Service practitioners who can prove intent to specialize before recruitment to the Forces and who were not established either in general or special practice are immediately eligible for Class III appointments be removed, and that Class III appointments under the Government's scheme be open to ex-Service practitioners who have made progress in the direction of specialism during their service with the Armed Forces.

The Association was informed that authority had been given to a scheme designed to help ex-Service practitioners both the fully qualified specialists able to take senior posts in hospitals without the need for supervision and also the more junior specialists not yet qualified to take full responsibility in a higher post.

For the former, local authorities and the larger voluntary hospitals were invited to increase their hospital establishments by creating additional whole time posts wherever the volume of specialist work justifies it. The salary of these posts will be met from the Exchequer and will be of the order of £1,000 a year. An assurance was given by the Department to the Council that these arrangements were not to be regarded as establishing any precedent, and that they were to continue only during the interim period pending the commencement of the new service. For the latter the Ministry proposed to enlarge the facilities for postgraduate training both by extending the duration of the appointments and, as far as may be practicable, by addition to the number of posts.

For those practitioners who, though unable to prove intent to specialize before recruitment have attained full specialist status in the Forces, the Ministry agreed that subject to approval by the deans and directors of postgraduate studies at the appropriate universities, Class III posts will be made available for them under the Government's scheme. Candidates selected by hospitals were required, in the first place, to serve for a probationary period of six months which was extended where the candidate was considered suitable for further training.

The Council feels that the flexible arrangement under which the graded specialist and the practitioner who gained a higher degree or diploma while serving with H.M. Forces is appointed to a Class III post after an appropriate period of training in a Class I post should be put into operation at all postgraduate centres administering the Government's scheme.

The Council has also urged that specialists and graded specialists in psychiatry who are in need of further training should be afforded an opportunity of taking Class III posts at mental hospitals where there is an out-patient clinic.

Study Groups

11 In accordance with the wishes of the A.R.M., 1946 the Council has advised Divisions to establish local study groups where these are not already in existence, in order to facilitate and encourage widespread discussion on medico-political problems and to attract the active co-operation of more practitioners in the formation of policy.

Gift by the late Sir Kaye Le Fleming

12 The Council has gratefully accepted a gift made by the late Sir Kaye Le Fleming of a portrait, a silver presentation porringer, and a framed collection of medals.

Committee of Inquiry into Health and Welfare and Safety of Persons in Places of Employment, and the Hours of Employment of Young Persons

13 A Joint Committee consisting of representatives of the Association, the Society of Medical Officers of Health, and the Association of Industrial Medical Officers was set up by the Council to prepare evidence for submission to the Departmental Committee which is considering the present statutory provisions relating to the health, welfare, and safety of workers in their places of employment and the hours of employment of young persons.

The Council approved the Memorandum of Evidence prepared by the Joint Committee. A copy will be sent to any member on request.

Code of Standards relating to Advertising of Proprietary Medicine

14 The Council has appointed a special Committee to consider and advise on the manner in which the Association could co-operate with the Newspaper Proprietors' Association and the Newspaper Society in the practical application of a code of standards concerning the advertisement in the lay Press of medicines and treatments.

Future Policy Regarding Alien Doctors

15 The Council was consulted by the Central Medical War Committee concerning proposals made by the Secretary of State for Home Affairs relating to the position of foreign medical practitioners in the United Kingdom whose professional activities are at present controlled by the Aliens Order. The practitioners concerned are

(i) Those who have British medical qualifications and have been allowed (or told that they will be allowed) to set up in independent private practice subject to Home Office approval of the place of practice;

(ii) Those who have British medical qualifications but are subject to a Home Office condition that they shall take only hospital posts or posts as assistants and shall not engage in independent practice;

(iii) Those who have no British qualifications but hold medical diplomas recognized by the General Medical Council for registration in the Temporary Register set up under Defence Regulation 32 B and

(iv) Certain Polish doctors who have been serving abroad as medical officers with the Polish Forces and therefore were not registered on the Temporary Register under the Defence Regulation.

Group (i) comprises the survivors of the 200 German refugee doctors who came here before 1936, and of the 50 Austrian and 50 Czech doctors who were selected by an Advisory Committee set up at the suggestion of the Secretary of State, and allowed to settle in practice here after obtaining British medical qualifications. Permission to set up in practice has been subject to Home Office approval of the place of practice.

Group (ii) includes a number of refugee doctors, perhaps about 150, who were not included in the limited quotas of specially selected refugee doctors, and a number of refugees who have taken all their medical training in the United Kingdom. Although these persons have acquired British

qualifications, the Secretary of State has felt bound by the pledge given to the profession by his predecessor not to allow them to settle in independent practice. They have, however, since the Temporary Registration Order was introduced, been allowed to take posts in hospitals or as assistants after consultation with the Central Medical War Committee as to location.

With regard to Group (iii) it is estimated that the total number who will be affected by the expiration of the Temporary Registration Order will be between 1,200 and 1,500, but this estimate may be subject to modification when more definite information is available of the number of Polish doctors registered under the arrangements referred to in the next paragraph.

With regard to Group (iv) the Government has accepted responsibility for the resettlement of the Polish Forces and their dependants either in the United Kingdom or elsewhere. Members of the Forces transferred to the United Kingdom are being enlisted in a Resettlement Corps of the British Army. It is proposed to ask Parliament to authorize a special reopening of the Temporary Register for the purpose of registration of those Polish practitioners not yet on the Register.

There is another small group of alien doctors who were locally commissioned in the R.A.M.C. overseas for employment in overseas theatres of war. They were allowed, if they wished, to be released in the United Kingdom, and in order to place them on the same footing as medical officers serving with the Polish Resettlement Corps the Temporary Register is to be opened for them.

The Council has expressed agreement with the following views of the Central Medical War Committee:

(a) That the establishment of alien doctors in independent private practice should continue to be subject to approval of the alien's choice of locality.

(b) That no objection should be raised to alien doctors with British medical qualifications being allowed the same professional freedom as *quoniam doctores*.

(c) That no objection should be raised to temporarily registered practitioners who have been approved, as outlined in paragraph (d) being placed on the permanent Register, and consequently being treated in the same way as other permanently registered alien practitioners.

(d) That a scheme should be worked out by the General Medical Council, in conjunction with representatives of the Ministry of Health, the Home Office and the Central Medical War Committee for the 'screening' of temporarily registered practitioners to be transferred to the permanent Register.

(e) That no objection should be raised to the reopening of the Medical Register to admit Polish medical officers enlisted in the Resettlement Corps, and ex R.A.M.C. alien doctors.

Psychiatry and the Law

16 The Council has received from the Joint Committee of the Association and the Magistrates' Association and has approved for publication a memorandum dealing with the social problem presented by the unstable adolescent girl who comes before the court on a charge of stealing or some other offence or because she is out of control or is in moral danger or in need of care and protection. The memorandum was published in the *Journal* of Dec 14, 1946, p. 909 and is being reprinted in booklet form. A memorandum on certification under the Mental Deficiency Acts which is associated with the problem of the unstable adolescent girl will be published at an early date.

The Council was recommended by the Joint Committee to pass resolutions in favour of the abolition of judicial corporal punishment both for juveniles and for adult offenders, but in view of the fact that the evidence adduced in support of the recommendation was in large part sociological and in small part medical the Council preferred not to express an opinion.

The Council has approved a memorandum prepared by the medical members of the Joint Committee on the law relating to attempted suicide and this will be published shortly.

Commemoration of the One Hundredth Anniversary of the American Medical Association

17 The American Medical Association will commemorate its One Hundredth Anniversary at meetings to be held at Atlantic City, New Jersey, from June 9 to 13, 1947. The

Council has gladly accepted an invitation to send delegates from the British Medical Association, and for this purpose the Council has appointed its Chairman (Dr H. Guy Dain), Dr J. A. Pridham, the Secretary, and the Editor.

Committee on the Elderly and Infirm

18 In accordance with the instruction contained in Minute 153 of the A.R.M., 1946, the Council has appointed a special committee to investigate the whole position in regard to the care and treatment of the elderly and/or infirm. This committee has been discussing questions of classification and nomenclature and collecting information about the existing provision of residential accommodation for the able-bodied and institutional care and treatment for the disabled. Representations have been made to the Ministry of Health on the importance of ensuring that new housing schemes include the provision of accommodation specially designed for elderly people, and of avoiding a segregation of the able-bodied elderly from the rest of the community.

Medical Curriculum Committee

19 The special Committee appointed in 1945 to review the medical curriculum in the light of the requirements of modern medical practice is proceeding with its task. It hopes to complete its report by the end of 1947.

NATIONAL HEALTH SERVICE ACT

20 The Government's Bill to provide for the establishment of a comprehensive health service for England and Wales was presented to the House of Commons on March 19, 1946, and, after a Second Reading debate on April 30, May 1 and 2, was committed to a Standing Committee. The proceedings in Standing Committee occupied twenty Parliamentary days, and the House of Commons passed the Bill on Friday, July 26, 1946. The Bill was considered in the House of Lords immediately on the resumption of Parliament after the summer recess and received its Second Reading there on Oct. 8 and 9. The Bill was committed to a Committee of the House of Lords. During this stage a Clause was added to the Bill to secure that the remuneration of general practitioners should be by the capitation method, save in exceptional circumstances. The Bill was passed by the House of Lords with this amendment on Nov. 1, 1946. The amendment was rejected by the House of Commons on Nov. 4, 1946, and, on reconsideration by the Upper House, was not insisted on. The Bill received the Royal Assent and became law on Nov. 6, 1946.

The main improvements secured by amendment during the progress of the Bill through Parliament may be summarized as follows:

(a) The Bill, as introduced, gave the Minister the power to change the constitution of the Central Health Services Council as a mere administrative decision. He now has to bring such changes before the House. The Bill empowered the Minister to suppress any part of the Council's advice. The Act requires him to consult the Council, if he proposes not to publish any part of its report.

(b) The individual hospital has been made a legal entity with power to receive money and other property, and will be able to sue or be sued in its own right. The Bill, as originally drafted, provided no legal hospital unit lower than a regional hospital board. Moreover, gifts made between the passing of the Act and the appointed day to existing voluntary hospitals will not be pooled when the service comes into operation, but will be transferred to the appropriate new management committee and that body may continue to apply these moneys according to the intentions of the donor.

(c) The Medical Practices Committee, in considering applicants for a vacancy in general practice, is to have regard to the wishes of an applicant to practise with other practitioners in an area, to any desire expressed by the existing practitioners to take an applicant into practice with them, and special regard to family relationships. The Minister is also required to have regard to these factors in determining appeals against the decision of the Medical Practices Committee.

(d) The oppressive provisions of the penal clauses in the Bill have been substantially lessened by the inclusion in the Act of a provision enabling a practitioner to ascertain in advance whether a proposed transaction involves, in the opinion of the

Medical Practices Committee, a sale of goodwill. If this Committee, on consideration of the facts is satisfied that a transaction does not involve considerations of goodwill, it is required to issue to the applicant a certificate to that effect, this will provide a defence if it is alleged subsequently that an offence has been committed.

On the passage of the Act the Negotiating Committee issued a report to its constituent bodies including a factual summary of the Act and a commentary based on the views expressed by the organized bodies of the profession. The issue which arose at this stage was whether or not discussions should be entered into with the Minister on the many matters to be dealt with by Regulations, including terms and conditions of service. In transmitting its report, the Negotiating Committee sought from each of its constituents an answer to this question. The Association decided to put this question to every member of the profession for decision by plebiscite. As a result of the plebiscite, a small majority of the profession expressed themselves against discussions on the regulations. The Special Representative Meeting on Jan 28, 1947, on consideration of the plebiscite results, expressed its willingness that discussions should be entered into with the Minister, provided that such discussions were comprehensive in their scope and that the possibility that they might lead to further legislation was not excluded.

The Negotiating Committee, early in February, decided to enter into discussions with the Minister on the basis of the Representative Body's decision. The Minister agreed to meet the Committee on this basis and, as an outcome of the meeting with him on Feb 28, the Negotiating Committee appointed six subcommittees to begin comprehensive discussions with the Ministry based on the resolution of the Representative Body. The subcommittees will deal with general practice, hospital and specialist services, public health services, mental health services, eye services, and superannuation respectively.

The Negotiating Committee at its meeting on Feb 7 decided that the representation of the British Medical Association on the Committee should be increased from 16 to 18 members. The present position is that of the 34 members of the Committee, 18 are appointed by the Association. The Association's representatives are

GENERAL PRACTICE

Fees for Medical Examinations in connexion with Life Insurance

21 The Council has considered the following Minute 20 of the Representative Body, 1946

"That the Council be empowered to terminate at the appropriate time the Agreement reached with the Life Offices' Association in 1919 in regard to the fees for medical examinations for life insurance."

Negotiations have been pursued with the Life Offices and the Industrial Life Offices Associations, and the following provisional agreement has now been reached with these bodies for a full examination and report the fee should in all cases be £1 11s 6d but in cases where the amount of the policy does not exceed £300 a standard shortened form of report may be used at a fee of 10s 6d. Thus, in the latter class of insurance the company may either use the standard short form or request a full examination at the higher fee.

In reaching this agreement the Council has drawn the attention of the Life Offices Association to the exceptionally lengthy form of medical report used by certain companies, and has intimated that it does not propose to recommend the acceptance of a fee of £1 11s 6d in these cases. It has been proposed that the forms in question should be suitably modified, or a fee of £2 2s paid for their completion, and this question is being pursued with the Life Offices Association.

Recommendation That Minutes 119-133 of the A R M 1920, and Minute 81 of the A R M, 1935, regarding the fees payable for medical examinations in connexion with life insurance be rescinded and the following substituted therefor

(1) That the following "Short" form of medical report be approved for use in the case of all insurances where the amount of the policy does not exceed £300, the fee for the completion of this form of report to be 10s 6d

(a) Does the Proposed appear in good health? Is his/her appearance consistent with the age stated?

(b) Is there any reason to suspect irregular or intemperate habits?

(c) Are there any abnormalities of the heart or lungs or pulse?

(d) Are there signs or symptoms of kidney disease? Result of urine examination Albumin Sugar

(e) Height of the Proposed Weight of the Proposed (If possible the Proposed should be weighed and measured by the Examiner)

(f) Are there any other circumstances not covered by the questions with which the Company should be acquainted? (e.g. In female cases, is she in an obvious state of pregnancy?)

(g) In which of the following classes would you place the risk?—First Second, Third *

* Classification 1st Class, lives acceptable on ordinary terms, 2nd Class, assurable, but only on special terms, 3rd Class, unassurable

(2) That for a medical examination and report in cases where the amount of the policy exceeds £300 the fee shall be £1 11s 6d

(3) That no attempt be made to standardize the £1 11s 6d form of report, but that where the form required by the Life Office is exceptionally extensive a fee of £2 2s should be payable

(4) That where, in the case of an insurance for an amount not exceeding £300, the Office requires a fuller examination than is provided in the "Short" form, the Office may use its ordinary form at a fee of £1 11s 6d

(5) That in all cases the fee appropriate to the examination, and the amount of the policy, should be printed on the form

Fees for Police Calls and for Attendance on Members of Police Forces

22 The Council has reviewed the question of the remuneration of practitioners for attendance on members of police forces. Occasionally this work is carried out by whole time police surgeons, but usually practitioners are appointed for the purpose on a part-time basis. The method of payment is by annual salary, capitation fee, or on a per case basis, and the amount of remuneration, whatever the method employed, varies considerably throughout the country. In a small number of areas, usually rural, a "free choice" system is in operation, the practitioner being remunerated either upon an agreed scale or in accordance with his normal charges.

In the opinion of the Council the most appropriate method of payment is a capitation fee not less than that paid to dispensing practitioners under the National Health Insurance Acts (excluding special drugs and appliances), but this method of payment should be restricted to police officers whose annual income does not exceed £420. In the case of police officers with incomes above £420 per annum it is considered that payment should be on a per-case basis as follows

Chief Constables and Assistant Chief Constables

Consultation	7s 6d
Day visit	10s 0d
Night visit and Sunday visit	
after 12 noon	£1 1s 0d

Superintendents and Inspectors

Consultation	5s 0d
Day visit	7s 6d
Night visit and Sunday visit	
after 12 noon	£1 1s 0d

Mileage at the rate of 1s per mile or part of a mile (each way) after the first two miles

Where the open choice method is in operation the Council recommends that the following minimum rates should be observed

Chief Constables and Assistant Chief Constables		All Other Ranks	
Consultation	7s 6d	Consultation	5s 0d
Day visit	10s 0d	Day visit	7s 6d
Night visit and Sunday visit		Night visit and Sunday visit	
after 12 noon	£1 1s 0d	after 12 noon	£1 1s 0d
With mileage as a separate item			

As regards the examination of candidates for the police forces and of police officers for pension purposes, it is considered that fees of £1 1s and 10s 6d respectively would be appropriate

Representations have been made to the Home Office with a view to securing the adoption of the foregoing rates for attendance on members of police forces throughout the country

The Council has also reviewed the existing policy of the Association regarding the fees which should be paid to practitioners called in by the police to make examinations and reports in connexion with criminal charges or to render emergency treatment. The fees now paid in many areas are totally inappropriate to the degree of responsibility involved. In some areas a composite fee is paid for the examination and report and subsequent attendance at court and sometimes a fee is payable only when the practitioner is required to attend court. In some areas the practitioner receives a lump sum payment or annual salary for attendance on members of the force and for examinations and reports. The Council considers the last mentioned method to be undesirable, while there is no objection to the payment of an annual salary or lump sum for attendance on the police, additional fees should be paid for examinations and reports

Recommendation That the following be substituted for the existing policy of the Association regarding remuneration of practitioners called in by the police

Where a medical practitioner is called in by the police in one of the following circumstances a fee not less than that stated below should be paid

(a) To examine a person charged with being in charge of a motor vehicle whilst under the influence of drink or a drug to such an extent as to be incapable of having proper control of the vehicle

Between the hours of 8 a.m. and 8 p.m.	£1 1s 0d
8 p.m. and 8 a.m.	£2 2s 0d
For report to the prosecuting solicitor	£1 1s 0d

If the examination takes an unusually long time, or the practitioner is required to remain at the police station for longer than three quarters of an hour in order that the defendant's own medical attendance may be called a supplementary fee of £1 1s 0d should be paid

(b) To examine a witness or person charged with or suspected of sexual offences

For the examination

Between the hours of 8 a.m. and 8 p.m.	£1 1s 0d
8 p.m. and 8 a.m.	£2 2s 0d

exclusive of the collection and examination of pathological specimens for which a higher fee should be paid

For report	£1 1s 0d
------------	----------

(c) To examine a witness or person charged with common assault

For the examination

Between the hours of 8 a.m. and 8 p.m.	12s 6d
8 p.m. and 8 a.m.	£1 5s 0d

If a special report is required an additional fee of £1 1s 0d should be paid therefor

(d) To examine a witness or person charged with assault with intent to commit grievous bodily harm including suspected rape or manslaughter

For the examination

Between the hours of 8 a.m. and 8 p.m.	£1 1s 0d
8 p.m. and 8 a.m.	£2 2s 0d
For report	£1 1s 0d

(e) To render emergency treatment to a person taken ill in the street, or a prisoner confined in the cells, to certify death in cases of "sudden death", and to examine a prisoner as to fitness for Borstal treatment

Between the hours of 8 a.m. and 8 p.m.	12s 6d
" " " " 8 p.m. and 8 a.m.	£1 5s 0d

The payment of the appropriate fees for the foregoing services should be irrespective of any subsequent action, and should not be combined with or included in the fee for attendance at court. Mileage should be paid at the rate of 1s per mile or part of a mile (each way) after the first two miles

Telephone Facilities for Doctors

23 The Council has considered the following Minute 44 of the Representative Body, 1946

Resolved That this meeting is of opinion that representations should be made to the Postmaster General that the telephone service should provide facilities at each exchange for taking messages during such times as a doctor may notify that his telephone will be unattended

The position has been discussed with the Postmaster-General, who has explained that a few years before the war the Post Office introduced an experimental service on these lines at one or two exchanges, but little use was made of it, and the war put an end to its development. Any wide reintroduction of such a service in London and the rest of the country would necessitate the employment of additional staff, and, especially at automatic exchanges, the provision of special equipment which at present is unobtainable. In these circumstances, and in view of the paramount need to meet the existing demands of new subscribers and to cope with the necessary arrears of repairs and replacements due to six years of war, the Postmaster-General sees no early prospect of resuming the experiments in providing a message-taking service

The only alternative, and one to which the Post Office would offer no objection would appear to be the operation of a private service. The Department has offered suggestions regarding the manner in which a satisfactory service could be established and a statement on this question was published in the *Supplement* on March 15 1947. Such a service, however, would be likely to prove expensive and would be practicable only in the larger centres

Medical Examination at the Request of an Insurance Company

24 The Council has considered the following Minute 24 of the Representative Body

Proposed by City That this meeting recommends that when a doctor is requested by an insurance company or a solicitor to be present at the examination of his patient by another doctor for the purpose of assessing a claim arising out of the patient's injury or illness, the fee payable should not be less than two guineas

The Council is of the opinion that it would be inadvisable to recommend a fee for this purpose in view of the fact that the circumstances vary from case to case. Sometimes the practitioner is required only to represent his patient, while at other times he is required to furnish information regarding the medical history of the patient. The Council considers, therefore that the question of assessing an appropriate fee should be a matter for arrangement between the practitioner and the insurance company or solicitor

Coroners' Acts

25 In accordance with the wishes of the Representative Body (Minute 46 of A.R.M.) the Council has appointed a special committee to review the operation of the Coroners Acts as they affect medical practitioners, and the committee has already begun its task

Remuneration of Civilian Medical Practitioners

26 The Council has again had under consideration the fees payable to civilian medical practitioners for occasional attendance on military personnel. It is not satisfied that the rates payable can be regarded as adequate at the present time, and accordingly the War Office has been urged to increase the fees

as follows and to abolish the daily maximum rate of £2 for all services rendered to the Department

Attendance and medicine	from 4s to 5s
Day visit up to 2 miles	" 6s " 7s 6d
Night visit up to 2 miles	" 10s " £1 1s

'Distance Fee' for day or night visit for each additional mile or part of a mile over 2 miles from 9d (one way) to 1s each way

The daily rates of remuneration of practitioners employed on full time or part-time duties have also been reviewed. These rates have not been increased since the beginning of the war and in the opinion of the Council are totally inappropriate. Representations have been made to the War Office that these rates should be increased as follows

Full time	from 30s a day (33s 6d a day where there is no Service M.O. at the station) to £5 5s a day
Part time	from 25s a day to £2 2s a day

Remuneration of Admiralty Surgeons and Agents

27 The Council has considered the following Minute 43 of the Representative Body, 1946

Resolved That the Council be asked to take action in order that the scale of fees paid to Admiralty Surgeons and Agents be revised to conform with the revised fees now paid by the Service Departments to Civilian Medical Practitioners in accordance with para 42 of Council's Report

The Council reports that representations on these lines had already been made to the Admiralty, and the Department has now sanctioned a revised scale of fees. The Council does not consider the fees now authorized to be adequate, and representations for their increase have been made

"Doctor" Signs on Cars

28 It will be remembered that as a wartime measure practitioners were encouraged to exhibit 'Doctor' signs on their cars to facilitate their movements in the interests of the public. Many practitioners are still exhibiting these signs on their cars despite the fact that the emergency no longer exists. The Council wishes to remind practitioners, therefore, that this practice can no longer be considered necessary or desirable, and the exhibition of "Doctor" signs on cars should be discontinued

Doctors' Maids

29 Owing to the relaxation of various wartime controls the Ministry of Labour and National Service is now unable to offer the same measure of assistance that was possible during the war to practitioners who experience difficulty in obtaining domestic help

The Council has accordingly asked various medical associations in European countries whether they can offer any help in putting British practitioners into touch with girls resident in foreign countries who are anxious to come to this country for the purpose of taking up domestic service. Unfortunately, the shortage of domestic servants is by no means restricted to Great Britain. The Austrian Medical Association has offered to compile a list of Austrian girls who are anxious to come to England for the purpose, and the Danish and Swiss Associations have also offered a limited degree of help. Practitioners desiring to employ foreign maids have been invited to communicate with the Secretary

Election of a Direct Representative on General Medical Council

30 An election will shortly be held to fill the vacancy on the General Medical Council caused by the death of Sir E. Kaye Le Fleming. As a result of a postal vote taken among the English and Welsh Representatives in the Representative Body Dr J. A. Brown (Birmingham) has been selected to receive the support of the Association in connexion with the forthcoming election

Surgical Corsets

31 The Council has discussed with the Board of Trade the possibility of relaxing the present controls on the supply of

surgical corsets. Owing to shortage of labour and materials the Board does not consider it possible at this stage to relax the restrictions. It has been agreed, however, that practitioners may give certificates for the supply of special corsets required for antenatal and postnatal conditions

Examination of Recruits to the Women's Land Army

32 As a result of representations made by the Council to the Ministry of Agriculture and Fisheries, the Department has agreed to increase the fee for the medical examination of candidates for the Women's Land Army from 5s to 10s 6d

Examinations of Dependants of Airmen

33 Representations have been made to the Air Ministry that the fees payable by the Department in cases where civilian medical practitioners are asked to examine airmen's dependants who are proceeding overseas should be increased as follows

Medical Examination	From 3s 6d for the wife, and 1s for each additional person—to 7s 6d per person examined
Vaccination	From 3s 6d to 7s 6d (including inspection)
Inoculation (No fee)	to 3s 6d (materials to be provided by the Department)
Mileage (No payment)	to 1s per mile each way after the first 2 miles

In reply the Air Ministry has explained that the examination required is simply an inspection to ensure that the individual is free from contagious or infectious disease and is otherwise fit to travel, and that each examinee will already have undergone medical examination to determine fitness for residence abroad. The Department therefore did not consider a fee of 3s 6d unreasonable but had decided to increase the fee for the inspection of additional persons from 1s to 2s 6d per head. Payment for inoculations was the responsibility of the individual, and the instructions were being amended to make this clear. Mileage would not be involved, as the applicants were required to visit the practitioners

In view of this explanation the Council has indicated to the Air Ministry that it is prepared to agree to a fee of 5s provided there is no reduction for the examination of additional persons

Remuneration of Medical Officers to Emergency Training Colleges

34 Consideration has been given to the remuneration of Medical Officers appointed to Training Colleges established for the emergency training of teachers, in connexion with which the Ministry of Education has laid down the following maximum rates for the guidance of Local Education Authorities

- 1 For medical attendance on pupils not eligible for treatment under the National Health Insurance Acts—10s 6d per session
- 2 For routine medical inspections at the end of the course, medical examinations of students referred to the Medical Officer by the Principal, and for giving general advice to the College on medical matters

Per College Session

9s 6d	in respect of each of the first 100 students
7s 6d	" " " " " second " "
5s 6d	" " " " " student in excess of 200

(A College "session" varies between 52 and 56 weeks during which time the students must work for at least 48 weeks)

It is understood that the capitation fee for treatment is now being brought into line with the present N.H.I. capitation fee. As regards the scale for services, other than treatment, the Council feels that the method employed is suitable for assessing remuneration for duties of different kinds in establishments of varying sizes. Alternative methods of payment would be by retaining fee plus a sessional fee, or by inclusive salary, and it would be difficult to lay down either a retaining fee or salary without relation to the size of the establishment. For these reasons the Council does not propose to raise any objection to the scale until it can be seen whether or not it offers an adequate remuneration for the duties involved

National Prescribers' Formulary

35 The Council in conjunction with the Council of the Pharmaceutical Society, has appointed a special Joint Committee composed of members of the medical and pharmaceutical

professions to compile a Standard Prescribers Formulary suitable for all branches of medical practice for use in connexion with the National Health Service. The Ministry of Health has accepted an invitation to appoint representatives to this committee. It is proposed that the Formulary shall be based on the formulary section of the *British Pharmaceutical Codex*.

Proposed National Health Service and the Position of Administrative Staffs and Collectors of Public Medical Services

36 The Council has endeavoured to secure from the Minister of Health an assurance that consideration would be given at the appropriate time to the position of the staffs of Public Medical Services who are likely to be displaced upon the coming into force of the National Health Service, both with regard to re-employment and compensation for loss of office. The Minister has indicated that he does not feel able to extend the provisions of the National Health Service Act regarding compensation for loss of office to the staffs of Public Medical Services. He has however expressed the desire that the fullest use should be made in the new service of experienced staff and that it would be his endeavour to see that the staffs of Public Medical Services should be found suitable employment in the new local bodies to be established.

Supplementary Clothing Coupons

37 The Council has considered the following Resolution of the Representative Body 1946

Resolved That the Council be instructed to press the Board of Trade to take such action as will improve the supply of operating gowns surgeons coats and overalls so that an issue of supplementary clothing coupons can be made with which to obtain these articles.

The Council reports that it has now been agreed by the Board of Trade that any practitioner who needs gowns in his private practice for obstetric work the treatment of venereal diseases operations or necropsies shall be entitled to obtain six surgeons operating gowns. Applications from practitioners in England and Wales should be made to the Ministry of Health from practitioners in Scotland to the Department of Health for Scotland and from practitioners in Northern Ireland to the Association.

Fees for the Administration of Anaesthetics to Persons Receiving Dental Treatment as an Additional Benefit under the National Health Insurance Acts

38 The Council has considered the fees payable to general practitioners for the administration of anaesthetics to persons receiving dental treatment as an additional benefit under the National Health Insurance Acts. The fees laid down for this purpose by the Dental Benefit Amendment Regulations (No. 2) 1946 are as follows

Administration of general anaesthetic fee per case in connexion with the extraction of

1-5 teeth	10s 0d
6-10 teeth	17s 6d
11-15 teeth	£1 5s 0d
16 or more teeth	£1 10s 0d

The Council does not consider this scale to be adequate particularly in view of the fact that the fee is per-case and not per-administration. After consulting the British Dental Association the Council recommends that the scale approved by the Joint Advisory Dental Council should be adopted with the proviso that it should be applied on a per-administration basis.

Recommendation That where practitioners are requested to administer anaesthetics to insured persons receiving dental treatment as an additional benefit under the National Health Insurance Acts the following fees should be paid

<i>Administration of general anaesthetic of 15 or less or</i>	
<i>1-5 teeth</i>	
1-5 teeth	10s 6d
6-10 teeth	£1 1s 0d
11-15 teeth	£1 11s 6d
16 or more teeth	£2 2s 0d

always provided that an increased fee shall be payable in specially difficult circumstances

Fees for Medical Certificates under the Lunacy and Mental Deficiency Acts, and for Recommendations under the Mental Treatment Act

39 The Council has considered the existing policy of the Association relating to the fees payable for certificates under the Lunacy and Mental Deficiency Acts, and for Recommendations under the Mental Treatment Act. The Council recommends

Recommendation (i) That the existing policy of the Association relating to the fees for medical certificates under the Lunacy and Mental Deficiency Acts, and for recommendations under the Mental Treatment Act, be rescinded

(ii) that there be substituted therefor the following

(1) *Fees for Medical Certificates under the Lunacy Acts*
A fee of at least two guineas should be paid

(2) *Fees for Medical Certificates under Mental Deficiency Act*
The fee for medical certificates under the Mental Deficiency Act, signed by the "usual medical attendant," should not be less than two guineas

(3) *Fees for Recommendations under Mental Treatment Act*
In cases where a recommendation is made under the Mental Treatment Act for a private patient the fee should be a matter of arrangement between the relatives and the practitioner concerned, but in public assistance cases a fee of not less than two guineas would appear to be appropriate

Fees for Certificates under the Cremation Act, 1902

40 The Council has reviewed the policy of the Association regarding the fee for the completion of certificates under the Cremation Act, 1902

Recommendation (i) That the following existing policy of the Association be rescinded

The fee for completing Form B under the Cremation Act (Certificate of Medical Attendant) should be a matter for private arrangement between the doctor and relatives concerned

The fee for completion of Form C (Confirmatory Medical Certificate) should be not less than one guinea

(ii) That there be substituted therefor the following

The fee for completing Form B (Certificate of Medical Attendant) and Form C (Confirmatory Medical Certificate) under the Cremation Act should be a matter for private arrangement.

Fees Payable to Examining Surgeons under the Factory Acts

41 The Council is glad to report that, following discussions with representatives of the Ministry of Labour and National Service on the question of the fees payable to Examining Surgeons, the Department has intimated that it proposes to recommend the following increases in the fees now paid to the British Employers Confederation where they are payable by industry, and to the Treasury where payable by the Department

	Existing Rate	Proposed Rate
<i>Examination of Young Persons</i>		
<i>(i) Examination at the factory</i>		
First case	5s 0d	7s 6d
Subsequent cases examined at the same time	2s 6d	4s 0d
<i>(ii) Examination at surgery</i>		
Each case	2s 6d	4s 0d
<i>Investigation and report on cases of Industrial Disease or Accident</i>		
First case	10s 6d	£1 1s 0d
Subsequent cases (where they arise in the same dept. of the factory and are dealt with at the same time)	5s	6d

Examinations of cases under the Dangerous Trades Regulations

First case	2s	6d	7s	6d
Subsequent cases	1s	0d	2s	6d

Mileage

At the rate of 1s per mile or part of a mile (each way) beyond a radius of 2 miles

Remuneration of Post Office Medical Officers

42 Consideration has been given to the following Minute 45 of the Representative Body, 1946

That the Council take steps to secure an increase of the visiting fee from 3s 6d to 5s and the abolition of the over-riding quarterly maximum of 14s paid by the Post Office to Post Office medical officers for attendance on postal employees living out of the district of their employment "

The Council has reviewed the whole question of the terms of service of Post Office medical officers and has made representations to the Postmaster General for a substantial increase in the capitation and other fees payable to Post Office medical officers. It is proposed also to discuss with the chief medical officer a number of administrative matters relating to the work of Post Office medical officers

In the meantime, the Postmaster General has indicated that it is proposed to grant a temporary increase in the capitation payment of 5s (bringing the fee to 18s 3d) with retrospective effect to Jan 1 1946

Remuneration of Ship Surgeons

43 The Council proposes to make representations to the Shipping Federation with a view to securing the adoption by all shipping companies of improved minimum rates of remuneration for ship surgeons employed on a permanent basis together with adequate provision for superannuation benefits for ship surgeons, and for free refresher courses on full pay and allowances

Remuneration of Members of Advisory Panels under the Disabled Persons (Employment) Act, 1944

44 The Council has made representations to the Ministry of Labour that the fee payable to members of Advisory Panels under the Disabled Persons (Employment) Act, 1944 be increased from £1 11s 6d to £2 5s per session

Regional Medical Officers

45 The Council is making representations to the Ministry of Health that the fee payable to Regional Medical Officers employed on a sessional basis be increased from £2 12s 6d to £3 3s per session

Part time Medical Officers to Small Establishments of the Ministry of Supply

46 The Ministry of Supply has decided to discontinue payment of its part-time medical officers to small establishments on a per-case basis, and to remunerate the practitioner concerned on a sessional basis. As a result of representations made by the Council, the Department has adopted the following scale

For an attendance up to half an hour	£1	0s	0d
Over half an hour up to 1 hour	£1	10s	0d
Over 1 hour, up to 1½ hours	£1	15s	0d
Over 1½ hours up to 2½ hours	£2	5s	0d
Over 2½ hours	£2	15s	0d

In cases involving attendance of a casual nature the Ministry has accepted the scale recommended to the War Office for occasional attendances upon soldiers on leave—i.e., consultation, 5s, day visit, 7s 6d, night visit, £1 1s with mileage at the rate of 1s per mile (each way) beyond a radius of 2 miles

INDUSTRIAL MEDICINE

47 The Annual Representative Meeting 1946, set up a new Standing Committee to consider and to report on matters affecting the practice of medicine in industry. The Minister of Labour has asked his Industrial Health Advisory Committee to prepare a practical scheme for the development of an industrial

medical service. The Council is preparing a memorandum on this matter

The Council has been informed of the desire of the National Ophthalmic Treatment Board to make the facilities of the National Eye Service available to the fullest possible extent to workers employed in industrial undertakings, and it has given advice on the practical steps which might be taken to attain this object. It has also considered a scheme for the provision in factories of a comprehensive ophthalmic service, with special emphasis on the treatment of injuries to the eye. It has approved the experimental establishment of ophthalmic services in industry for the examination of refractions, the supply of spectacles and such minor treatment as is at present provided by the National Eye Service, but it considers that the moment is not opportune for the establishment of a comprehensive accident service

National Insurance (Industrial Injuries) Act, 1946

The Council has noted with satisfaction that the National Insurance (Industrial Injuries) Act, 1946, gave effect to many of the proposals made by the Association for the modification of the Workmen's Compensation Act

REHABILITATION**Pensioners and Rehabilitation**

48 The Council has considered the question of the fitness for work and earning capacity of patients who are undergoing rehabilitation treatment in an institution

Under the National Insurance (Industrial Injuries) Act 1945, when an injured person enters any hospital or similar institution for the purpose of receiving approved hospital treatment his incapacity is assessed at 100% even if the degree of disablement in respect of which a pension is payable is less than 100%. Treatment allowances are made accordingly. If however, the patient receives payment for any work he does while he is in hospital a reduction is made in the treatment allowances. This is an important matter in the problem of rehabilitation, and the Council is of opinion that a scheme of graduated remunerative employment should be provided for during the transition stage from hospital to workshop without prejudice to the patient's treatment allowances

The Council has accordingly made representations to the Ministry of Health that

1 Provision should be made for persons receiving rehabilitation treatment in an institution to undertake remunerative employment while under treatment on a scale increasing with his physical capability,

2 The patient should be allowed earnings for such work up to a maximum of 80% of his normal pre injury earnings

3 In view of the fact that such employment offers an incentive to increased working and earning capacity and is likely to ensure earlier return to ordinary employment, no deductions should be made from treatment allowances on account of earnings for such employment

NATIONAL HEALTH INSURANCE**Insurance Capitation Fee**

49 The application, in the early part of 1946, for an increase in the capitation fee was the first of a series of events which reached a climax in the autumn and eventually resulted in a settlement which was acceptable to the general body of insurance practitioners. The Spens Committee's report was issued soon after the application was made, and it was regarded as the basis upon which a settlement of the capitation fee could be reached. The Minister of Health, however, sought to impose the condition that negotiations for remuneration under the future health service must precede consideration of proper remuneration for the current National Health Insurance Service. Interviews and correspondence with the Ministry on the subject concluded with an intimation from the Ministry that, as this condition was unacceptable to the profession, the Minister had decided to increase the fee to 12s 6d (from Jan 1, 1946) while negotiations were proceeding on the long term agreement. This was a challenge which had to be accepted and preparations were made for a general withdrawal from the service unless the Minister was willing fully to apply the Spens report

to the current capitation fee, with effect from Jan 1 1946 or refer the matter to the Spens Committee or a representative section of that committee or other agreed independent body eventually the Minister agreed to discussions taking place on the basis of the Spens report with special reference to the current capitation fee.

The terms of the settlement with effect from Jan 1 1946 are

1 The increase recommended by the Spens Committee excluding the special measures affecting rural practices, is taken as equivalent to an average for all general practitioners of £162 (This if taken in full would equal 3s 3d on the capitation fee.)

2 Of this increase 90% is accepted by the Ministry as attributable to insurance practice. This figure is based on the view that while undoubtedly by far the largest part of the underpayment of doctors before the war as found by the Spens Committee is applicable to health insurance remuneration it is nevertheless fair to attribute a small part of this underpayment to other practice.

3 Allowing betterment at 30% on the gross fee we get	we get
Capitation fee (1939)	s d
Spens increase (90% of 3s 3d)	9 0
	2 11
	11 11
Betterment (30%)	3 7
	15 6

The betterment figure takes account of increases in medical practice expenses and cost of living since 1939.

The Ministry has said that these calculations involve figures which will have a bearing on any future negotiations concerning the new service, but it has been made clear to the Ministry that acceptance by the profession is without prejudice to the remuneration in any future service and to the factors to be employed in its assessment.

Mileage

50 There has also been an increase in the Mileage Fund so as to take account of the special measures for rural practitioners recommended in the Spens report. The amount that is to be added to the Mileage Fund (including the Highlands and Islands Fund) is £236 280 making a total of £615 380 or 72% above the total in 1939.

Dispensing Capitation Fee

51 An application has been made for a substantial increase in the capitation fee for insured patients for whom a doctor is required to supply all necessary medicines and prescribed appliances.

Postgraduate Courses for Insurance Practitioners

52 The Ministry of Health has reintroduced the postgraduate courses for insurance practitioners on the lines of similar courses available in 1938-9 pending the provision of such facilities under the proposed National Health Service. The courses are made possible by the willingness on the part of the universities to continue during 1947 the courses of postgraduate instruction for demobilized doctors.

As in the case of similar courses before the war the syllabus will be subject to the general approval of the Minister of Health. An insurance practitioner will be given freedom of choice of the centres where courses are available. In the case of a specialized subject the Ministry will exercise its veto only in cases where the subject is considered to be inappropriate.

An insurance practitioner will be allowed to take one two week course during 1947 or two one week courses. To be eligible for financial assistance he must (a) have at least 300 insured patients on his list or 100 if practising in an urban area or 150 if practising in a rural area (b) have been registered for at least three years and (c) not have entered one of the courses for demobilized officers.

Financial assistance towards the expenses of insurance practitioners will be paid out of National Health Service funds. Such expenses will include a grant for the provision of a laboratory where necessary, the fee for the course, the cost of travelling to and from the course and the cost of the expenses.

Medical Records of Demobilized Persons

53 Arrangements have been made for doctors to obtain a précis of the medical record of a demobilized person subject to the patient's permission being obtained. These Service medical histories are held by and obtainable from the appropriate Service Department.

Penicillin

54 With a view to ensuring the economic use of penicillin the Ministry has been asked to make available to insurance practitioners direct facilities for the examination of pathological specimens.

Certification

55 An increasing number of employers are requiring the production of NHI certificates as evidence of incapacity for work. This is regarded as an improper practice, especially in view of the statement printed on every official form—"these certificates are to be used for National Health Insurance purposes only." The Insurance Acts Committee has on many occasions asked the Ministry to take appropriate action in this matter, and has recently received a reiteration of previous replies to the effect that the Department does not feel that it is practicable to prohibit this practice, which could and should be stopped. The subject is again being pursued with the Ministry.

Recruitment of Doctors—Protection of Practices

56 At the request of the Panel Conference the question of hardship among doctors who are being called up for the Forces, either as specialists or for general duty, has been under consideration. It is understood that the number of doctors in general practice now being compulsorily recruited is extremely small, and it is doubtful whether the situation calls for any widespread protection of practices arrangement. It is felt that the interests of general practitioners are being carefully watched by their colleagues on Local Medical War Committees and by the Services Committee of the Central Medical War Committee and that satisfactory arrangements of an *ad hoc* nature could be made for the protection of the practice of any doctor who is in need of such assistance.

Shortage of Medicaments

57 The attention of the Ministry of Health has been drawn to the inadequacy of the present supplies of liquid paraffin, olive oil, glucose, and tulle dressings.

SPECIAL PRACTICE

Consultant-Specialist Spens Committee

58 The Minister of Health has expressed his intention of setting up a committee under the chairmanship of Sir Will Spens to consider the range of remuneration of consultants and specialists. It will consist of five representatives of the medical profession, five lay members selected by the Minister of Health and the Secretary of State for Scotland, and an independent chairman. The views of the Association were invited upon the terms of reference of the committee, and after consultation with representatives of the English Royal Colleges and the Scottish Royal Corporations it was suggested to the Minister that the terms of reference should be as follows:

"To consider, after obtaining whatever information and evidence it thinks fit, what ought to be the range of total professional remuneration of registered medical practitioners engaged in the different branches of consultant or specialist practice in any publicly organized hospital and specialist service, to consider this with due regard to what have been the financial expectations of consultant and specialist practice in the past, to the financial expectations in other branches of medical practice, to the necessary postgraduate training and qualifications required, and to the desirability of maintaining the proper social and economic status of specialist practice and its power to attract a suitable type of recruit having regard to other forms of medical practice, and to make recommendations.

The Minister has accepted this suggestion and proposes to set up the new committee without delay. The three English

Royal Colleges and the Association have jointly nominated for membership of the committee Lord Moran of Manton, Prof Harry Platt (Manchester) Dr S Cochrane Shanks (London) and Mr J R H Turton (Hove)

A special committee—the Evidence Committee on Remuneration of Consultants and Specialists—has been appointed to collaborate in the preparation of evidence on behalf of consultants and specialists generally. The committee consists of the Consultant and Specialist Services Subcommittee of the Negotiating Committee (enlarged by the addition of six non-teaching consultants and six additional representatives of the Scottish Royal Corporations) and the Consultant Services Subcommittee of the Consultant Services (Beveridge) Committee

Part-time Consultants and Specialists

59 Consideration has been given by the Council to the following Minute 49 of the A R M 1946

Min 49 Resolved That, whilst approving paragraph 51, this meeting requests Council to take action passed by A R M July, 1945 (Min 71), in order to allay the present widespread apprehension

Minute 71 of the A R M, 1945, requested the Council to inform part-time consultants and specialists on hospital staffs what steps were being taken to safeguard their position and future employment, and was taken into consideration by the Council in establishing the constitution of the new Consultants and Specialists Committee, which provides for representation of part-time consultants and specialists. The Council endorses the opinion expressed in paragraph 51 of the Annual Report to the A R M 1946 that the interests of part-time consultants and specialists are best safeguarded by their representation on the Consultants and Specialists Committee and it is taking steps to ensure that the existence, within the Association, of the Roll of Part-time Consultants, and the right of members included in that roll to participate in the election of five representatives to the Consultants and Specialists Committee are brought to the notice of all concerned

Employment of Junior Specialists Released from H M Forces

60 Arising out of Council's approval of a recommendation of the Dermatologists Group Committee a communication has been sent to the Director of the British Post Graduate Federation drawing attention to the difficulties encountered by ex-Service practitioners under the Government's postgraduate scheme, and emphasizing the need for the training of dermatologists. It urged that supernumerary registrarships should be created wherever possible to provide adequate training facilities in dermatology for junior specialists demobilized from the Services, who should be encouraged while holding these appointments to study general medicine up to the M R C P standard

The Standing Committee on Dermatology of the Royal College of Physicians is being informed of the Council's view that in all dermatological clinics of teaching hospitals there should be available one or more registrarships, to which practitioners would be appointed for one year having annual tenure and subject to the possibility of re-election. The hope was expressed that, while under present circumstances these appointments would usually be given to ex-Servicemen, this class of practitioner would continue to receive special consideration under full peacetime conditions

Training of Dermatologists in H M Forces

61 The Council has approved a recommendation of the Dermatologists Group Committee concerning the training of medical officers in H M Forces who wish to become specialists in dermatology as distinct from venereology. The Directors-General of the three fighting Services have accordingly been invited to recognize the general trend to regard dermatology as a separate specialty divorced from venereology and requested to give consideration to this principle in the planning of the post-war organization of the medical services of the armed Forces

Rules for the Government of Groups and Consultants Part-time Consultants' Rolls

62 In consequence of the replacement of the Specialist Practice Committee by the Consultants and Specialists Committee the Council has found it necessary to revise the Rules for the Government of Groups and to establish new Rules relating to Rolls of Consultants and Part-time Consultants. In this connexion it had before it the following Minute of the A R M 1946

48 Proposed by West Suffolk (H M Bird) That reference to paragraph 50 of the Council's Report local to the Consultant and Specialist Groups should be open to a vote of consultants and specialists whether whole or part time

The Council is of the opinion that, while it is desirable that provision should be made for regional meetings open to whole-time and part-time consultants or specialists and to members and non-members of the Association, it is also desirable that the right of members of the Consultants Roll to hold seats at regional meetings should be maintained

Consultant Services Committee

63 An inquiry has been received from the Royal College of Physicians as to the effect the establishment of the Consultants and Specialists Group Committee would have upon the Consultants' representation on the Consultant Services Committee of the College which had previously included all members of the Consultants and Specialists Group Committee for England and Wales. To meet the new situation the Council has informed the College that members of the Consultants and Specialists Committee elected regionally for England and Wales, together with the Chairman of Council and the Secretary are nominated as members of the Consultant Services Committee

Post mortem Facilities

64 The following principles for the provision of a satisfactory post-mortem service have been agreed with the Association of Clinical Pathologists, the Coroners Society and the Medico Legal Society

(a) That arrangements be made to ensure that all necropsies undertaken at the request of coroners be performed by competent practitioners having special experience and training in the performance of necropsies and further having at their disposal facilities of a pathological laboratory, always providing that the selection of the practitioner shall be made at the discretion of the coroner

(b) That all necropsies should be made in properly equipped post mortem rooms such as are found in hospitals

(c) That the performance of coroners' necropsies should be centralized and so arranged that the cadaver be brought to the practitioner rather than the practitioner to the cadaver

(d) That mortuaries for the temporary housing of cadavers near the place of death will continue to be required but these should not be equipped for the performance of necropsies

(e) That arrangements be made for a copy of the coroners' report on a necropsy to be sent to the practitioner in previous attendance on the case

(f) That the date and time of a necropsy be notified by the coroner to the practitioner in previous attendance on the case in order that he may be given an opportunity to attend the examination

These recommendations will be incorporated in the report of the Association's Coroners Acts Committee

Safeguards for Consultants and Specialists under a National Health Service

65 The A R M 1946 approved a number of proposals submitted by the Council for safeguarding the position of consultants and specialists under a National Health Service. The Council has considered the matter afresh in the light of certain suggestions made at that meeting (Minute 51 of A R M) and has made appropriate amendments to meet the position. The report on this matter has now been referred to the Negotiating Committee, and will be taken into consideration in the discussions with the Department

Pensions Appeal Tribunals Rules

66 In its report to the A.R.M. 1946 the Council indicated that it was not satisfied with the reply received from the Lord Chancellor's office to representations for an increase in fees for medical witnesses and certificates under the Pensions Appeal Tribunals (England and Wales) Rules 1943. On further consideration, however, it was felt that there had been some understanding of the Lord Chancellor's recommendation and approval has accordingly been given to the following increases in the maximum fees payable under Part II of the Second Schedule of the Rules

- (1) To increase from £2 2s to £3 3s the fee for the attendance of a medical witness before the Tribunal
- (2) To increase from 5s to £1 1s the fee for medical certificates and reports obtained by the appellant

Occupational Therapy and Mental Nurses

67 Representations were made to the Ministry of Health in support of a resolution of the Royal Medico-Psychological Association expressing the opinion that occupational therapy when carried out by a mental nurse is a nursing duty and should be recognized as such. In reply the Ministry has stated that by agreement between the Association of Occupational Therapists and the Mental Hospitals Association the question of the salary and conditions of service of occupational therapists has been referred to the Joint Negotiation Committee on Salaries and Wages (Hospital Staffs), and that it has been agreed that a qualified mental nurse holding a post as occupational therapist should be regarded primarily as an occupational therapist rather than as a mental nurse.

The Council has expressed the opinion that, while it is desirable that the mental nurses curriculum should include some training in occupational therapy, only those recognized by the appropriate body as being fully trained and qualified in occupational therapy should be entitled to describe themselves as occupational therapists and to occupy posts as such.

Salaries of E.M.S. Specialists

68 As it is likely that appointments of pathologists under the E.M.S. will continue until the introduction of a National Health Service, representations have been made to the Ministry of Health that such pathologists should continue to receive regular increments of pay on reaching the maximum in their present range of salary. The Ministry has replied that authority had been obtained for further increases in the remuneration of officers remaining enrolled in the Emergency Medical Service pending the inception of the National Health Service. The basic ranges of Specialists (£800-£900), Medical Officers (£550-£650) and the Junior Medical Officers (£350-£450) will be extended by annual increments of £30 until the Emergency Medical Service is wound up.

The Council has also considered the position of E.M.S. officers who have been paid throughout at fixed basic salaries above £800 because of their additional responsibility as Superintendents of Hospitals, Officers-in-Charge of Medical or Surgical Divisions etc. the amounts above £800 being in the nature of allowances. A lump-sum increase of £100 is now authorized for officers in this group who had completed four years in their present posts prior to July 1 1946 £80 for three years and £50 for two years.

The arrangement applies not only to pathologists but also to other specialists and medical officers whose services in the E.M.S. are retained.

Scales of Fees for Radiological Services

69 The Council has approved the following scale of fees for radiological cases referred by local authorities to voluntary hospitals in substitution for that which has been in existence since 1938

	£	s	d
Examination of chest upper and lower extremities (one area)	2	2	0
Pelvimetry antenatal examinations without pelvic examinations of teeth hip pelvis spine (one area) skull urinary tract, and gall bladder	3	3	0

In cases requiring special examinations—e.g., stereography, tomography, and all examinations requiring contrast media the fee shall be arranged between the radiologist and the local authority.

This is a special scale of reduced terms for contract work and should not be taken as constituting the fee for private practice.

Consideration has also been given to the scale of modified charges for radiological services at hospitals approved in 1939. This scale, which was based upon an average of one-half the fees commonly charged for similar private work in the district, recommended minimum charges for patients examined in hospital who were within certain income limits, provided they were being seen by other consultants at similarly reduced fees. As the Council is of the opinion that the scale no longer serves any useful purpose and that the present time is inopportune for the formulation of a revised scale of fees of this kind it has abolished the scale.

Rules for the Government of the Consultants and Part-time Consultants' Rolls

70 The Council has further considered the exclusion from membership of the Roll of those members of the Association who are whole-time officers in the public health service. The Council has decided that clinicians in the public health service should not now be excluded from the Roll and has amended the Rules accordingly.

Access to Ancillary Departments of Hospitals

71 The Council has considered an amendment to paragraph 57 of its last report carried by the A.R.M. 19-6 to the effect that experience having shown that the advantages of the policy of the 'open door' outweigh the disadvantages it should be adopted as a uniform system throughout the country.

The Consultants and Specialists Committee and individual Group Committees have been consulted and the Council is of opinion that a distinction should be made between diagnosis and therapeutic facilities, and considers that facilities for diagnosis and treatment control should be made directly available to general practitioners whether in hospital or elsewhere.

Problems and Needs of Certain Groups in Academic Medicine

72 A memorandum on the problems and needs of certain groups in academic medicine has been prepared by the Committee of the Group of Full-time Non-professional Medical Teachers, Laboratory and Research Workers. This memorandum, with the approval of Council has been sent to the University Grants Committee.

Fees Paid by Government Departments for the Services of Medical Specialists

73 Consideration has been given by the Council to Minutes 55-57 of the A.R.M., 1946 referring back that part of its Annual Report relating to the revised scale of fees offered to the Ministry of Pensions for cases referred to specialists. Information has been obtained from the various Government Departments relating to fees paid by them to consultants and specialists and regard has been had to the agreement with the Ministry of Health and local authorities of the revised scale of remuneration for medical practitioners employed part-time by local authorities. The Council considers this scale to be appropriate one for adoption by all Government Departments employing specialists on a sessional basis and instructions have been given for the necessary representations to be made.

HOSPITALS

Payment of Voluntary Hospital Staffs

74 The Council has continued its consideration of the desirability of adequate salaries being paid to the visiting specialist staffs of voluntary hospitals during the interim period before the introduction of the National Health Service. In November 1946 it decided to recommend that without prejudice to any arrangements these staffs should receive salaries assessed on a basis of five guineas for a session.

d a circular conveying this recommendation was issued to Medical Staff Committees. The matter is now being reconsidered in the light of the agreed scale of fees recently negotiated for part-time work undertaken by consultants and specialists for local authorities and discussions on the subject are being held with the British Hospitals Association. The Ministry of Health has been urged to provide financial assistance to those hospitals which are unable to pay adequate salaries out of their own funds. The Council hopes that it may very soon be in a position to communicate again with Medical Staff Committees, announcing arrangements agreed with the Ministry and with the B.H.A.

Disabled Persons (Employment) Act, 1944

75 The Council has been consulted by the Ministry of Health regarding a new scheme recommended by the Medical Advisory Committee of the National Advisory Council on the Employment of the Disabled for the purpose of bringing hospitals and employment exchanges into close relation in the matter of placing disabled persons in employment. This scheme includes two proposals. The first is to introduce a new and greatly simplified form of medical certificate for use by hospitals in respect of patients about to be discharged with some residual disability. This form will be completed by a member of the medical staff at the hospital and sent to the employment exchange for use in connexion with any application made by the patient under the Disabled Persons (Employment) Act for registration or for advice on training or employment. For the completion of this short form of certificate a fee of 2s 6d is proposed.

The second proposal is to set up Medical Interviewing Committees to advise on cases in which a more detailed examination and report prove to be necessary. Initially these MICs consisting of two members, will be established only experimentally at selected hospitals in a few areas. Two doctors holding responsible positions in the hospital, and having some knowledge of the problem of rehabilitation and resettlement will be appointed to the MIC, the one to act as Chairman and the other as Deputy Chairman in his absence. The second member of the MIC will be a doctor with industrial experience—e.g. a factory examining surgeon, a general practitioner with knowledge of industry and occupational health, or an industrial medical officer. A Disablement Resettlement Officer will attend the Committee and discuss with it the industrial implications of the medical findings and recommendations. Exceptionally, at the discretion of the Chairman, arrangements will be made for a specialist to attend the Committee or for a patient to be referred to him. General medical practitioners will be informed of the MIC facilities and encouraged to refer patients in need of advice regarding employment. The fees proposed for those serving on the MICs are under discussion.

Hospital Treatment of Ministry of Pensions Patients

76 The Ministry of Pensions following the example of the Ministry of Education, offered to pay for hospital treatment of patients for whom it is responsible at the rates set out in Ministry of Education Circular 102 with which the Representative Body expressed dissatisfaction last July. Now that decisions have been taken as to the revised terms to be recommended to the Ministry of Education the Council is urging the Ministry of Pensions to alter its terms in accordance with these new proposals.

House Officers—Restriction on Future Practice

77 The Council has had under consideration the question of restrictions being placed on a house officer in regard to practice in the area served by the hospital after the termination of his hospital appointment. Its view is that it is undesirable that the terms of service of a resident hospital officer should include any restrictive condition relative to future practice in the locality.

Provident Funds

78 The Council has suggested to the Nuffield Provident Guarantee Fund the advisability of the Classification of Operations drawn up by the Fund in agreement with the Association being revised. It has consulted the Guarantee Fund about the possibility of providing provident fund cover for treatment of

mental conditions by some of the newer techniques such as pre-frontal leucotomy and convulsion therapy. The Guarantee Fund has replied that while it considers it impossible to admit liability for treatment of all mental disease the governing body of a provident fund has discretion to make ex-gratia payments, on the advice of its medical referee, towards the cost of treatment of mental disorder before certification. The Council has also taken up with the Guarantee Fund the question of raising the age limit for membership of provident funds above 60 and has suggested the desirability of the age limit being the highest compatible with the actuarial possibilities.

Liaison with the Nursing Profession

79 The Liaison Committee with the Royal College of Nursing, the establishment of which was reported by the Council last year has held a number of useful meetings. Among the matters it is considering are the professional status of the nurse, the doctor-nurse relationship, and the qualifications which should be required of a candidate for admission to a course of training for the nursing profession.

PUBLIC HEALTH

Salaries in the Public Health Service

80 Discussions have just begun between the Negotiating Committee and the Minister of Health on the sections in the National Health Service Act 1946, relating to the Public Health Service including Section 66, which empowers the Minister to make regulations with respect to the qualifications, remuneration, and conditions of service of, among others, medical officers in the service of local health authorities. It is intended that the scales drawn up by the Council and referred to in paragraph 130 of the Supplementary Annual Report of Council to the A.R.M., 1946 should form the basis of the negotiations on remuneration and conditions of service for all medical officers in the public health service. As only County Councils and County Borough Councils are local health authorities under the Act the Negotiating Committee has been requested to deal with these matters in relation to medical officers employed by other local authorities as well.

The Council has received an invitation to participate in discussions between the local authority associations, the employers' side of the National Joint Council for Local Authorities Administrative, Professional, Technical and Clerical Services, and the societies of chief officers on the salaries of chief officers in the local government service, including medical officers of health as distinct from other medical officers. The Council has not accepted the invitation, as acceptance would involve a departure from the policy established by the Askwith agreement of dealing with medical officers as a whole. The Council has however agreed to send observers to the discussions, which are proceeding. As a result of this development it has been emphasized to the Negotiating Committee that in any negotiations the Public Health Service should be regarded as a whole and the remuneration of all its members negotiated together by the same negotiating machinery.

In order that the existence of proposals for future remuneration in the Public Health Service might receive publicity among local authorities, copies of the scales referred to above have been forwarded to all whole time medical officers of health. It was felt that this action might also help to correct any impression that the revised Askwith scales were intended to be permanent.

The Interim Revision of the Askwith scales which came into operation as from April 1 1946, has never been regarded as satisfactory for the senior grades, many of whom under its terms have benefited only to a small extent, while others have not benefited at all. It was accepted as an emergency measure in order to secure an immediate improvement for those in the lower grades. The Negotiating Committee has accordingly been requested to take steps to secure a substantial all round improvement.

Salaries in the Mental Health Service

81 As a sequel to the agreement with the local authority associations on a revision of the Askwith scales on a percentage basis and as an interim measure pending the settlement of new

permanent scales, the following agreement has been concluded with the Mental Hospitals Association for those medical officers employed at mental hospitals and mental deficiency institutions not coming within the scope of the Askwith interim revision

(1) The salaries of medical officers in mental hospitals and institutions for the mentally defective (other than assistant medical officers already dealt with in the interim revision of the Askwith memorandum) shall be increased as follows

(a) if the datum salary does not exceed £700, by 30% of that salary,

(b) if the datum salary exceeds £700, but does not exceed £1,000, by 20% of that salary

(c) if the datum salary exceeds £1,000, by 10% of that salary

provided that no officer shall have an automatic entitlement to a total salary greater than that produced by the addition to the maximum of the scale of pay as at Sept 3 1939, attached to the position he occupies of the appropriate percentage increase of the datum salary for the position

(2) For the purposes of the foregoing paragraph datum salary shall,

(a) subject to adjustment as provided in (c) below, be for officers in service on Sept 3, 1939 (and continuously employed thereafter to the date of issue of this Memorandum) the minimum of the scale of salary attached to the material position at Sept 3 1939,

(b) subject to adjustment as provided in (c) below, be for officers appointed after Sept 3, 1939 the minimum of the scale of salary attached to the material position either at Sept 3, 1939, or at the date of appointment, whichever is the lower

Note to (a) and (b)

(i) Wartime service shall not be regarded as breaking the continuity of appointment

(ii) Where there is no scale and the officer has been in office for some years regard should be had to increments, which he has received during the few years preceding 1939, for the purpose of determining a national scale. If there have been no increments the salary in operation is the commencing salary for the purposes of this agreement

(c) be assessed on a resident basis and shall be the net cash amount remaining after (A) deduction of the individually agreed charges for board, lodging, and washing where gross salaries subject to deductions for residential amenities if provided, are payable and/or (B) exclusion of the value of emoluments provided in kind or services,

(d) not include any payment made in respect of possession of the DPM

(3) Individual cases where there is doubt should be referred for joint consideration by the Mental Hospitals Association (or the employing authority concerned if not a member of the Mental Hospitals Association) and the British Medical Association

(4) The foregoing arrangements, which are without prejudice to any subsequent negotiations upon scales of remuneration in the National Health Service and are in addition to war bonus, are to have effect as from April 1 1946

(5) Marginal adjustments shall be made to ensure that an officer to whom a 20% increase applies shall receive a revised salary of not less than £910 per annum, and that an officer to whom a 10% increase applies shall receive a revised salary of not less than £1,200 per annum, and in the case of incremental scales the amount of the increase, as adjusted be applied throughout the scale

(6) In cases where present salaries are such as to disqualify their recipients either in whole or in part, from receipt of the salary increases now agreed employing authorities clearly have discretion to review existing rates of remuneration

The above revision took effect as from April 1 1946. It is similar so far as the percentages are concerned to the Interim Revision of the Askwith Memorandum and as in the case of the latter revision the Council has requested the Negotiating Committee to endeavour to secure a further interim improvement

Practitioners Employed Part-time by Local Authorities

82 The Council has held conferences, under the aegis of the Ministry of Health with the local authority associations with a view to obtaining their agreement to the scale approved by the ARM 1946 for the remuneration of medical practitioners employed part-time by local authorities. Agreement was ultimately reached on a scale which, although it does not

entirely correspond with that approved by the ARM, does represent a considerable advance on the old scale, and in some respects a very considerable advance on the remuneration actually paid by individual local authorities. The local authority associations have recommended their constituent authorities to adopt the scale with effect from Nov 1, 1946. They realize that this agreed scale like the revision of the Askwith memorandum for whole-time medical officers, cannot be regarded as more than an interim arrangement without prejudice to future negotiations, and they have so informed their constituent authorities

In order that the agreed scale might be circulated and brought into operation at the earliest possible moment the Council gave its approval pending confirmation by the Annual Representative Meeting

Recommendation That notwithstanding the scale adopted by the ARM, 1946, for the remuneration by local authorities of medical practitioners employed by them on a part-time basis, the scale set out below be approved as an interim measure dating from Nov 1, 1946 and without prejudice to future negotiations

REMUNERATION ON A SESSIONAL BASIS FOR SESSIONS OF NORMALLY 1½ TO 2½ HOURS

1 *Consultants and Specialists*—For all regular consultant and specialist sessions at hospitals and clinics, including (a) administration of anaesthetics, (b) treatment of venereal diseases, (c) x-ray examination and treatment, including ringworm, (d) adenoid and tonsil operations, (e) examination and certification of blind school children, (f) ophthalmic work for school children. Regular weekly individual, occasional, or additional sessions and emergency attendances £4 4s per session or attendance. These rates are intended for application to all persons possessing the necessary qualifications and experience, and it is recognized that higher remuneration should be paid where senior consultants are required for work carrying special responsibilities. A reduced fee of 2½ guineas should be paid for sessions of not more than one hour—i.e., which do not normally exceed one hour

Mileage—A mileage allowance of 1s per mile each way should be paid a medical practitioner for every mile outside a radius of two miles calculated from his home or from any centre from which he practises, whichever is the less, and provided that no charge shall be made in respect of any distance travelled for which he receives or has claimed an allowance otherwise

2 *General Practitioners*—Regular weekly individual, occasional, or additional sessions and emergency attendances £2 5s per session or attendance. A reduced fee of £1 10s should be paid for sessions of not more than one hour—i.e., which do not normally exceed one hour

3 *Refractionists*—Where a local authority enters into an arrangement with any medical practitioner to perform clinical refraction work only, the rate of pay for such work should in all cases be £2 17s 6d per session

REMUNERATION ON A PAYMENT-PER-CASE BASIS

Consultants and Specialists

4 *Surgical Operations*—The fee payable to a surgeon not under contract with the local authority and called in to operate in an emergency, including emergency domiciliary obstetrical operations, should be related to the services rendered, and should not in any case be less than £5 5s for a minor operation and £10 10s for a major operation with a mileage allowance as proposed in section 1. Where an emergency operation is performed as an immediate result of a consultation and during the same visit, only the operation fee, and mileage as proposed in section 1 shall be paid

5 *Consultations*—The fee payable for a consultation at the request of a local authority for work not covered under section 1 should be £4 4s and a mileage allowance as proposed in section 1 shall also be paid

6 *X-ray Treatment of Ringworm*—Where the local authority refers cases to the radiologist at his private clinic £4 4s per case

7 *Blind Persons Act Certificates*—In all cases where sessional arrangements are impracticable the fee should be £2 2s and a mileage allowance as proposed in section 1

General Practitioners

8 *Antenatal and Postnatal Examination*—(i) 7s 6d for each antenatal or postnatal examination (ii) 12s 6d for each examination and report to the local authority if requested by the local authority

9 *Diphtheria Immunization*—(i) The material to without cost by the local authority (ii) Fee for

at a doctor's surgery 3s 6d per injection (iii) Fee for visiting a child at home and giving injections there 6s a visit (iv) Mileage would not usually be paid in respect of visits to the patient's home, it being contemplated that normally such visits will occur in the course of the doctor's practice, but in exceptional cases there should be a mileage allowance as proposed in section 1

Administration of Anaesthetics

10 For the administration of an anaesthetic the fee should depend on the length of the operation and on the anaesthetic used and be from £1 10s

Other Services

11 For services not mentioned above, for example, lectures in respect of consultants, specialists, and general practitioners the rate of remuneration should be arranged after consultation between the local authority and the local Division or Branch of the British Medical Association

Advisory Committee

12 The Advisory Committee established under Part X of the Askwith Agreement shall hear and advise upon any applications for the settlement of differences or the clarification of points of obscurity

Saving for Better Conditions

13 Nothing in these recommendations shall prevent a medical practitioner from continuing his present contractual arrangements with a local authority in lieu of those enumerated above

National Joint Council for Local Authorities

83 The Council's attention has been drawn to attempts made by certain local authorities to apply to medical officers a scheme prepared by the National Joint Council for Local Authorities Administrative, Professional, Technical, and Clerical Services relating to the remuneration and conditions of service of such staff. The Council's attitude is that medical officers, for whom the Association is the recognized negotiating body where salaries and conditions of service are concerned, are outside the province of the National Joint Council, on which in any event the Association is not represented. Steps have been taken to secure official recognition of this view

Milk

84 As instructed by the A R M, 1946, the Council has conveyed the following resolution to the Ministry of Health and also to the Department of Health for Scotland

"119 Ideally all milk should be obtained from disease free herds under the best hygienic conditions. In the meantime all milk should be pasteurized or, where efficient pasteurization is not available, boiled, and that this should be emphasized immediately to the Minister as a matter of urgent national importance

The Ministry of Food has appointed a Committee with the following terms of reference

'To examine the distribution of liquid milk from the point at which it leaves the farm to the point at which it is received by the consumer or manufacturer and to advise on any changes which are necessary to ensure that clean, safe milk is delivered as efficiently and cheaply as possible'

At the invitation of the Ministry a deputation from the Council attended before the Committee to present the Association's views on clean milk

Public Assistance District Medical Officers

85 As a result of the National Insurance Act and the National Health Service Act, few, if any, duties will remain to be carried out by Public Assistance District Medical Officers. The Council is of opinion that, in order to avoid any risk of compensation being prejudiced by reduced remuneration resulting from a diminution of duties, it is desirable that the service should be wound up, that the former duties of District Medical Officers should be absorbed into the National Health Service, and that adequate compensation for loss of time should be paid to the medical officers for loss of office, the compensation being based on the remuneration received before the winding up. The Negotiating Committee's attention has been drawn to this view

Education Act

86 The A R M 1946, passed the following resolution

175 That this meeting is dissatisfied with the payments for in patient treatment of children under the Education Act and presses the Council to draw up an equitable scale of remuneration

The Council had intended, when the scale for local authority part time work generally was settled, to reopen with the Ministry of Education the subject of fees payable by local education authorities for the treatment of school children. Now that the scale has been agreed proposals based as far as possible on it have been submitted to the Ministry for the revision of the fees for the treatment of school children

Trade Union Membership

87 As a result of the repeal by the Trade Disputes and Trade Unions Act, 1946, of the Trade Disputes and Trade Unions Act, 1927 it is no longer illegal for a local or public body to require as a condition of employment of any person that he should or should not be a member of a trade union. Certain local authorities have taken advantage of the new Act to impose on their employees, in some cases including medical officers, a requirement, amounting to a condition of employment, that they should become members of a trade union or other organization. Their resolutions fall into three categories (i) requiring membership of a trade union or professional organization, (ii) requiring membership of a trade union, or (iii) requiring membership of a trade union affiliated to the TUC

The Council, after careful consideration of the position created, has drawn up the statement of policy set out in the recommendation below. Pending the approval of the A R M, the Council, in view of the urgency of the matter, is acting in accordance with these principles in connexion with advertisements for the *Journal*

In cases where action has been taken by the Council it usually happens that the local authority concerned eventually rescinds its resolutions or makes them inapplicable to medical officers

Recommendation That the following statement be approved as the policy of the Association in relation to compulsory membership of trade unions and other organizations, so far as medical officers are concerned

1 The B M A, representing the great majority of doctors and enjoying a membership of over 55,000, is the negotiating body for the medical profession, recognized as such by the Ministry of Health and the Associations of Local Authorities in England and Wales

2 In the view of the Association it is undesirable on principle that any practitioner should be required to join any body, B M A or other. The Association prefers that its membership should remain voluntary, the strength of the Association remaining an expression of the profession's confidence in its representative body

3 Where an authority imposes upon its officers or candidates for office a requirement of a membership of a particular body or bodies, B M A or other (but excluding a medical defence society), the Association should protest to such authority, and afford financial help to any practitioner who suffers as a result of accepting the advice of the Association. All advertisements for whole time public health medical officer or part time appointments of such authorities submitted by such authorities for publication in the *British Medical Journal* shall be rejected and the profession advised not to make applications for such posts. The medical Press should be asked to co operate

Fees for Attendance at Confinements

88 The Council has considered the following resolution of the A R M, 1946

'That this meeting is of opinion that the minimum fee for attending a full confinement under local authority arrangements should be £5 5s

The term "full confinement" is not used in the regulations prescribing the existing scale and it appeared to be in need of definition. In forwarding the resolution to the Ministry of Health, therefore, the words "and subsequent visits during the first fourteen days inclusive of day of birth" were added after the words "full confinement". The Council has taken the opportunity of reviewing the remainder of the fees in the First Schedule of the Medical Practitioners (Fees) Regulations, 1940 and has formulated and forwarded to the Ministry, the following scale with a request that the regulations be amended accordingly

(i) Fee for all attendances of a medical practitioner at any time from the commencement of labour until the child is born, whether or not operative assistance is involved, including all subsequent visits to mother and/or child during the first fourteen days inclusive of

the day of birth, £3 3s. Provided that where only one attendance is made in the period from the commencement of labour until the child is born and the practitioner is not present at the birth or subsequently a fee of £2 2s shall be payable in lieu of the fee of £3 3s aforesaid.

(ii) Fee for attendance of a second medical practitioner to give an anaesthetic, whether on the occurrence of abortion or miscarriage, at parturition or subsequently, £1 1s.

(iii) Fee for all or any of the following, namely, suturing the perineum, removal of adherent or retained placenta, exploration of the uterus, treatment of post-partum haemorrhage or any operative emergency arising directly from parturition, including all subsequent necessary visits during the first fourteen days inclusive of the day of birth, £1 11s 6d. This fee not to be payable when a fee under paragraph (i) hereof is payable.

(iv) Fee for attendance at, or in connexion with, an abortion, miscarriage, haemorrhage in cases of threatened abortion or ante-partum haemorrhage,* including all visits in respect of such attendance during the fourteen days from and including the first visit, £1 11s 6d.

(v) Fee for visits to mother and/or child not included under paragraphs (i) to (iv) hereof.

Where attendance is given to the mother only or to the child only

	s	d
Day (9 a.m. to 8 p.m.)	5	0
Night (8 p.m. to 9 a.m.)	10	0

Where attendance is given to both the mother and child

	s	d
Day (9 a.m. to 8 p.m.)	7	6
Night (8 p.m. to 9 a.m.)	15	0

(vi) The usual mileage fee of the district to be paid for all attendances under paragraphs (i) to (v) hereof.

Provided that one mileage fee only shall be paid in respect of one journey, whether such journey shall have been made for visiting one, or more than one, patient.

(vii) Fee for attendance on mother or child at the medical practitioner's residence or surgery, 2s 6d.

(viii) The practitioner shall be reimbursed the cost of any specially expensive drugs provided by him.

* Haemorrhage after the twenty eighth week of pregnancy.

Children and Young Persons Act, 1933

89 In 1939 the A.R.M. approved fees for the guidance of practitioners and local authorities in connexion with the provision of medical attention for children committed to the care of local authorities and boarded out by them under the Children and Young Persons (Boarding Out) Rules 1933, made by the Secretary of State in pursuance of Section 84 of the above Act. The Council has considered the desirability of revising these fees and has drawn up a scale which is consistent with similar items in the local authority part-time scale (paragraph 82 above) and the scale for practitioners called in by midwives (paragraph 88).

Recommendation. That the following scale of remuneration be approved—in substitution for that approved by the A.R.M. 1939—for practitioners undertaking the initial medical examination and subsequent attendance on children committed to the care of a local authority and boarded out under the Children and Young Persons (Boarding Out) Rules, 1933.

(a) For initial medical examination and report 12s 6d.

(b) For subsequent medical attendance (including supply of medicines),

(i) At surgery, 7s 6d first consultation, 5s each subsequent consultation.

(ii) At home of child 10s 6d first visit 7s 6d each subsequent visit.

In addition a fee of 1s per mile each way outside a radius of 2 miles from practitioner's residence or surgery where a journey cannot be fitted in with ordinary practice.

"BRITISH MEDICAL JOURNAL"

90 At the time of last year's Report the weekly printing order for the *Journal* was 55,500 copies. The printing order is now 62,000. The more readers the *Journal* has the greater is the demand for space in it by members and subscribers. It may be noted that in 1938 the average weekly total of pages amounted to 144, and in 1946 to 68. With the paper ration fixed the *Journal* has managed to include between its two covers all its principal features by reducing the proportion of

pages allocated to advertisements, and by the use of smaller sizes of type. Matters were eased somewhat when the paper ration was increased in October, 1946, and it might have been expected that this favourable turn of events would continue, but the fuel crisis of February, 1947, put the clock back. We were prevented from printing the *Journal* for the two weeks ending Feb 22 and March 1 and when we resumed normal publication we were informed we should not be allowed to use the paper which would have been consumed during these two weeks. On top of this there was a cut of 12½% in the paper ration. The situation is serious, as the continued increase in membership of the Association carries with it an obligatory increase in the print order of the *Journal*. We took advantage of the more liberal allowance of paper towards the end of 1946 to print certain sections of the *Journal* in larger type. During the war there were many complaints from readers that the type sizes used in the *Journal* were too small for visual comfort. If, however, we are faced with the position of a mounting print order and a diminishing supply of paper we may have to revert to the smaller sizes of type familiar to readers during the war years.

At no time since 1939 have those responsible for the *Journal* and the Quarterly Journals been faced with so many difficulties in connexion with paper and printing. In particular, there has been a serious delay in publication of five of the Quarterly Journals published by the Association, and the editors of these journals have expressed their dissatisfaction with the position. The Editor and the Publishing Manager have taken all possible steps to meet a situation unprecedented during the many years the Association has published periodicals other than the *British Medical Journal*. The printer of five of the Quarterly Journals released three of these to another printer in order to ease the pressure. Owing to the extreme difficulty in obtaining art paper it was agreed with the Editors of the Quarterlies that the letter press of their journals should be printed on super-calendered paper such as is used for the *Journal* and that the art paper available should be shared out among them for the reproduction of half-tone illustrations. In spite of these and other expedients there is still delay in the publication of the Quarterly Journals, and it will be some time yet before we can expect to return to normal.

To begin publishing two new monthly journals—*Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology*—in January, 1947, in the face of the difficulties mentioned was a somewhat hazardous undertaking. We had hoped that these journals would appear on the first of each month, and the work was so planned in the *Journals* Abstract Department as to make this possible. But considering the obstacles and frustrations confronting anyone trying to do a job of work in these days we may be satisfied that the delay in appearance of the Abstract Journals has in no instance been longer than 18 days. The quality of printing is high, and the format and arrangement of material seem to have met with approval. It is perhaps out of place for us to say that the quality of the work has also been high but again this seems to be the opinion of those who have received these journals. The acid test is circulation, and this has exceeded expectations in the first three months of publication. Special credit for this new venture is due to the Editor of *Abstracts* Dr G. M. Findlay, and the Assistant Editor Dr S. S. B. Gilder, supported as they are by a competent and hard-working team and a large panel of abstracters, upon whose co-operation the success of the abstracting service depends.

We should perhaps record here a unique event in the history of the *Journal*. On Sunday Feb 9, we learnt that owing to the fuel crisis it might not be possible to print the *Journal* of Feb 15. It was not until Tuesday morning, Feb 11 that we could discover from the Ministry of Fuel and Power whether or not that issue of the *Journal* could go to press. On the same day it was announced that for the two weeks following Feb 15 all weekly periodicals would be suspended. This decision was reached as a result of agreement between the Ministry of Fuel and Power and the Periodical Trade Press and Weekly Newspaper Proprietors Association, an organization which had refused membership to the *Journal* in 1938 on the ground that it was not an independent journal. The ban was extended to publication of...

1 doctor's surgery 3s 6d per injection (iii) Fee for visiting child at home and giving injections there 6s a visit (iv) Mileage would not usually be paid in respect of visits to the patient's home, it being contemplated that normally such visits will occur in the course of the doctor's practice, but in exceptional cases there should be a mileage allowance as proposed in section 1

Administration of Anaesthetics

10 For the administration of an anaesthetic the fee should depend on the length of the operation and on the anaesthetic used and be from £1 10s

Other Services

11 For services not mentioned above, for example, lectures in respect of consultants, specialists, and general practitioners the rate of remuneration should be arranged after consultation between the local authority and the local Division or Branch of the British Medical Association

Advisory Committee

12 The Advisory Committee established under Part X of the Askwith Agreement shall hear and advise upon any applications for the settlement of differences or the clarification of points of obscurity

Saving for Better Conditions

13 Nothing in these recommendations shall prevent a medical practitioner from continuing his present contractual arrangements with a local authority in lieu of those enumerated above

National Joint Council for Local Authorities

83 The Council's attention has been drawn to attempts made by certain local authorities to apply to medical officers a scheme prepared by the National Joint Council for Local Authorities Administrative, Professional, Technical, and Clerical Services relating to the remuneration and conditions of service of such staff. The Council's attitude is that medical officers, for whom the Association is the recognized negotiating body where salaries and conditions of service are concerned, are outside the province of the National Joint Council, on which in any event the Association is not represented. Steps have been taken to secure official recognition of this view

Milk

84 As instructed by the A.R.M., 1946, the Council has conveyed the following resolution to the Ministry of Health and also to the Department of Health for Scotland

"119 Ideally all milk should be obtained from disease free herds under the best hygienic conditions. In the meantime all milk should be pasteurized or, where efficient pasteurization is not available, boiled, and that this should be emphasized immediately to the Minister as a matter of urgent national importance

The Ministry of Food has appointed a Committee with the following terms of reference

'To examine the distribution of liquid milk from the point at which it leaves the farm to the point at which it is received by the consumer or manufacturer and to advise on any changes which are necessary to ensure that clean, safe milk is delivered as efficiently and cheaply as possible'

At the invitation of the Ministry a deputation from the Council attended before the Committee to present the Association's views on clean milk

Public Assistance District Medical Officers

85 As a result of the National Insurance Act and the National Health Service Act, few, if any, duties will remain to be carried out by Public Assistance District Medical Officers. The Council is of opinion that, in order to avoid any risk of compensation being prejudiced by reduced remuneration resulting from a diminution of duties, it is desirable that the service should be wound up, that the former duties of District Medical Officers should be absorbed into the National Health Service, and that adequate compensation for loss of time should be paid to the medical officers for loss of office, the compensation being based on the remuneration received before the winding up. The Negotiating Committee's attention has been drawn to this view

Education Act

86 The A.R.M. 1946, passed the following resolution

173 That this meeting is dissatisfied with the payments for in patient treatment of children under the Education Act and presses the Council to draw up an equitable scale of remuneration'

The Council had intended, when the scale for local authority part time work generally was settled, to reopen with the Ministry of Education the subject of fees payable by local education authorities for the treatment of school children. Now that the scale has been agreed, proposals based as far as possible on it have been submitted to the Ministry for the revision of the fees for the treatment of school children

Trade Union Membership

87 As a result of the repeal by the Trade Disputes and Trade Unions Act, 1946, of the Trade Disputes and Trade Unions Act, 1927, it is no longer illegal for a local or public body to require as a condition of employment of any person that he should or should not be a member of a trade union. Certain local authorities have taken advantage of the new Act to impose on their employees, in some cases including medical officers, a requirement, amounting to a condition of employment, that they should become members of a trade union or other organization. Their resolutions fall into three categories (i) requiring membership of a trade union or professional organization, (ii) requiring membership of a trade union, or (iii) requiring membership of a trade union affiliated to the TUC

The Council, after careful consideration of the position created, has drawn up the statement of policy set out in the recommendation below. Pending the approval of the A.R.M., the Council, in view of the urgency of the matter, is acting in accordance with these principles in connexion with advertisements for the *Journal*

In cases where action has been taken by the Council it usually happens that the local authority concerned eventually rescinds its resolutions or makes them inapplicable to medical officers

Recommendation That the following statement be approved as the policy of the Association in relation to compulsory membership of trade unions and other organizations, so far as medical officers are concerned

1 The B.M.A., representing the great majority of doctors and enjoying a membership of over 55 000, is the negotiating body for the medical profession, recognized as such by the Ministry of Health and the Associations of Local Authorities in England and Wales

2 In the view of the Association it is undesirable on principle that any practitioner should be required to join any body, B.M.A. or other. The Association prefers that its membership should remain voluntary, the strength of the Association remaining an expression of the profession's confidence in its representative body

3 Where an authority imposes upon its officers or candidates for office a requirement of a membership of a particular body or bodies, B.M.A. or other (but excluding a medical defence society) the Association should protest to such authority, and afford financial help to any practitioner who suffers as a result of accepting the advice of the Association. All advertisements for whole time public health medical officer or part time appointments of such authorities, submitted by such authorities for publication in the *British Medical Journal* shall be rejected and the profession advised not to make applications for such posts. The medical Press should be asked to co-operate

Fees for Attendance at Confinements

88 The Council has considered the following resolution of the A.R.M. 1946

'That this meeting is of opinion that the minimum fee for attending a full confinement under local authority arrangements should be £5 5s

The term 'full confinement' is not used in the regulations prescribing the existing scale and it appeared to be in need of definition. In forwarding the resolution to the Ministry of Health therefore the words "and subsequent visits during the first fourteen days inclusive of day of birth" were added after the words 'full confinement'. The Council has taken the opportunity of reviewing the remainder of the fees in the First Schedule of the Medical Practitioners (Fees) Regulations, 1940, and has formulated and forwarded to the Ministry, the following scale with a request that the regulations be amended accordingly

(i) Fee for all attendances of a medical practitioner at any time from the commencement of labour until the child is born, whether or not operative assistance is involved, including all subsequent visits to mother and/or child during the first fourteen days inclusive of

the day of birth, £3 3s. Provided that where only one attendance is made in the period from the commencement of labour until the child is born and the practitioner is not present at the birth or subsequently a fee of £2 2s shall be payable in lieu of the fee of £3 3s aforesaid.

(ii) Fee for attendance of a second medical practitioner to give an anaesthetic, whether on the occurrence of abortion or miscarriage, at parturition or subsequently, £1 1s.

(iii) Fee for all or any of the following, namely, suturing the perineum, removal of adherent or retained placenta, exploration of the uterus, treatment of post partum haemorrhage or any operative emergency arising directly from parturition including all subsequent necessary visits during the first fourteen days inclusive of the day of birth, £1 11s 6d. This fee not to be payable when a fee under paragraph (i) hereof is payable.

(iv) Fee for attendance at, or in connexion with, an abortion, miscarriage, haemorrhage in cases of threatened abortion or ante-partum haemorrhage,* including all visits in respect of such attendance during the fourteen days from and including the first visit, £1 11s 6d.

(v) Fee for visits to mother and/or child not included under paragraphs (i) to (iv) hereof.

Where attendance is given to the mother only or to the child only

	s	d
Day (9 a.m. to 8 p.m.)	5	0
Night (8 p.m. to 9 a.m.)	10	0

Where attendance is given to both the mother and child

	s	d
Day (9 a.m. to 8 p.m.)	7	6
Night (8 p.m. to 9 a.m.)	15	0

(vi) The usual mileage fee of the district to be paid for all attendances under paragraphs (i) to (v) hereof.

Provided that one mileage fee only shall be paid in respect of one journey, whether such journey shall have been made for visiting one, or more than one, patient.

(vii) Fee for attendance on mother or child at the medical practitioner's residence or surgery, 2s 6d.

(viii) The practitioner shall be reimbursed the cost of any specially expensive drugs provided by him.

* Haemorrhage after the twenty-eighth week of pregnancy.

Children and Young Persons Act, 1933

89 In 1939 the A.R.M. approved fees for the guidance of practitioners and local authorities in connexion with the provision of medical attention for children committed to the care of local authorities and boarded out by them under the Children and Young Persons (Boarding Out) Rules 1933, made by the Secretary of State in pursuance of Section 84 of the above Act. The Council has considered the desirability of revising these fees and has drawn up a scale which is consistent with similar items in the local authority part-time scale (paragraph 82 above) and the scale for practitioners called in by midwives (paragraph 88).

Recommendation. That the following scale of remuneration be approved—in substitution for that approved by the A.R.M. 1939—for practitioners undertaking the initial medical examination and subsequent attendance on children committed to the care of a local authority and boarded out under the Children and Young Persons (Boarding Out) Rules, 1933.

(a) For initial medical examination and report 12s 6d.

(b) For subsequent medical attendance (including supply of medicines)

(i) At surgery 7s 6d first consultation 5s each subsequent consultation.

(ii) At home of child 10s 6d first visit, 7s 6d each subsequent visit.

In addition a fee of 1s per mile each way outside a radius of 2 miles from practitioner's residence or surgery, where a journey cannot be fitted in with ordinary practice.

"BRITISH MEDICAL JOURNAL"

90 At the time of last year's Report the weekly printing order for the *Journal* was 55 500 copies. The printing order is now 62 000. The more readers the *Journal* has the greater is the demand for space in it by members and subscribers. It may be noted that in 1938 the average weekly total of pages amounted to 144 and in 1946 to 68. With the paper ration fixed the *Journal* has managed to include between its two covers all its principal features by reducing the proportion of

pages allocated to advertisements, and by the use of smaller sizes of type. Matters were eased somewhat when the paper ration was increased in October, 1946, and it might have been expected that this favourable turn of events would continue, but the fuel crisis of February, 1947, put the clock back. We were prevented from printing the *Journal* for the two weeks ending Feb. 22 and March 1 and when we resumed normal publication we were informed we should not be allowed to use the paper which would have been consumed during these two weeks. On top of this there was a cut of 12½% in the paper ration. The situation is serious, as the continued increase in membership of the Association carries with it an obligatory increase in the print order of the *Journal*. We took advantage of the more liberal allowance of paper towards the end of 1946 to print certain sections of the *Journal* in larger type. During the war there were many complaints from readers that the type sizes used in the *Journal* were too small for visual comfort. If, however, we are faced with the position of a mounting print order and a diminishing supply of paper we may have to revert to the smaller sizes of type familiar to readers during the war years.

At no time since 1939 have those responsible for the *Journal* and the Quarterly Journals been faced with so many difficulties in connexion with paper and printing. In particular, there has been a serious delay in publication of five of the Quarterly Journals published by the Association, and the editors of these journals have expressed their dissatisfaction with the position. The Editor and the Publishing Manager have taken all possible steps to meet a situation unprecedented during the many years the Association has published periodicals other than the *British Medical Journal*. The printer of five of the Quarterly Journals released three of these to another printer in order to ease the pressure. Owing to the extreme difficulty in obtaining art paper it was agreed with the Editors of the Quarterlies that the letterpress of their journals should be printed on super-calendered paper such as is used for the *Journal* and that the art paper available should be shared out among them for the reproduction of half-tone illustrations. In spite of these and other expedients there is still delay in the publication of the Quarterly Journals, and it will be some time yet before we can expect to return to normal.

To begin publishing two new monthly journals—*Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology*—in January, 1947, in the face of the difficulties mentioned was a somewhat hazardous undertaking. We had hoped that these journals would appear on the first of each month, and the work was so planned in the *Journal's* Abstract Department as to make this possible. But considering the obstacles and frustrations confronting anyone trying to do a job of work in these days we may be satisfied that the delay in appearance of the Abstract Journals has in no instance been longer than 18 days. The quality of printing is high, and the format and arrangement of material seem to have met with approval. It is perhaps out of place for us to say that the quality of the work has also been high, but again this seems to be the opinion of those who have received these journals. The acid test is circulation, and this has exceeded expectations in the first three months of publication. Special credit for this new venture is due to the Editor of *Abstracts* Dr G. M. Findlay, and the Assistant Editor, Dr S. S. B. Gilder, supported as they are by a competent and hard-working team and a large panel of abstracters, upon whose co-operation the success of the abstracting service depends.

We should perhaps record here a unique event in the history of the *Journal*. On Sunday, Feb. 9, we learnt that owing to the fuel crisis it might not be possible to print the *Journal* of Feb. 15. It was not until Tuesday morning, Feb. 11, that we could discover from the Ministry of Fuel and Power whether or not that issue of the *Journal* could go to press. On the same day it was announced that for the two weeks following Feb. 15 all weekly periodicals would be suspended. This decision was reached as a result of agreement between the Ministry of Fuel and Power and the Periodical Trade Press and Weekly Newspaper Proprietors Association, an organization which had refused membership to the *Journal* in 1938 on the ground that it was not an independent journal. The ban was extended to publication.

we discovered that the ban had no force in law and therefore decided to produce the issues of the *Journal* for Feb 22 and March 1 in duplicated form, and without the use of electricity. This was made possible by the wholehearted co-operation of the Secretary of the B.M.A. and his staff, who put at the disposal of the Editor duplicating machines and willing workers. At the time of the issue of the two *Pennine Journals* there was considerable comment on this in the Press. That the action taken was approved by members of the B.M.A. was shown by the large number of letters received at B.M.A. House. The *Journal* was in fact the only weekly journal of any size and standing not to be deceived by the Government's bluff and by what was nothing more or less than arbitrary censorship through temporary suspension of publication.

FINANCE

91 The interim financial statement for the year 1946 which is subject to audit, shows an increase of income of £11,592 and an increase of expenditure of £40,870.

Balance Sheet

As war risks insurance is no longer payable, the balance of the reserve for this purpose has been added back to the surplus account. The sum of £20,000 has been added to the general contingency reserve. Assets have been increased by the investment of £31,000 in dated Government stock.

Income and Expenditure Account Expenditure

The appointment of new and important committees has necessarily led to an increase in central meeting expenditure and it must be anticipated that this will increase still further in the coming year. Included in the Association General Expenditure is the cost of the Public Relations Department which was considerably less than the sum appropriated by the Council, and legal charges which include the counsel's fees paid for advice in regard to the proposed National Health Service. The increase in income tax on dividends and interest is complementary to the additional revenue received from investments. Capitation grants increased in proportion to the rising membership and to the restoration to the Home Branches of members returning from the Forces. Central staff expenses show an increase, the Council having implemented its proposals in regard to regional development by additions to the secretariat.

As regards premises expenses it is still not possible to obtain licences for work other than that regarded by the authorities as absolutely essential, but during the year the ventilation of the council chamber has been carried out in addition to minor decorations to offices and the maintenance of lifts and other services throughout the building. There was a substantial increase in the cost of printing stationery and postages as a result of the plebiscite and the issue to the profession of statements on the proposed National Health Service.

Income

At the close of 1946 the membership stood at a new record of 54,175, and the revenue from the subscriptions reached £123,356. Through the return of members to civilian practice and the consequential payment of a higher subscription the average subscription received for the year increased from £2 4s 2d in 1945 to £2 5s 6d. There was a small increase in the revenue received from rents which now exceed £20,000 per annum. Decisions which have been taken in regard to the accommodating of various departments in the extensions to B.M.A. House and Garden Court wing will lead to a loss in revenue, but this will be met to a large extent by the application of the new scale of rentals when negotiating new tenancies.

Journal Account

The Journal Account again shows a substantial increase in the revenue from advertisements and publishing. The number of advertisement pages increased from 1,068 in 1945 to 1,218 in 1946. A substantial increase in the number of copies published was again necessary, rising from 2,795,700 in 1945 to 3,021,900 in 1946.

Trust Funds

The Office Staff Superannuation Fund, in common with all holders of gilt edge stock, is having to accept conversions which yield a lower rate of interest. At the same time the financial position of the fund is sound, the market value of investments on Dec 31, 1946, standing at £53,779. The Prize Funds, for which the Council acts as trustees, all hold balances sufficient to meet the cost of the prizes to be awarded during the coming year. The B.M.A. Charities Trust Fund has maintained its income and has been able to make substantial allocations to the medical charities. As a result of a special appeal, the Medical Representation in Parliament Fund has now received support which will enable it to give financial assistance to medical candidates for Parliament.

Estimate of Receipts and Expenditure for the Year 1947

It may reasonably be hoped that the revenue of the Association will increase during the present year to £155,000. It seems certain, however, that, because of the steadily increasing activities of the Association and the increasing cost of commodities and services there will be a considerable rise in expenditure. Nevertheless, it is confidently anticipated that a credit balance will be achieved. The subscriptions of its members are the main source of the Association's income. The extensions of the Association's work to which it is committed will soon bring the level of its expenditure to that of its income. The time is approaching when an increase in the subscription rates, fixed at their present level as far back as 1922, may have to be considered.

MEDICAL ETHICS

Ethical Procedure relative to "Important" Notices

92 The Council has considered Minute 183 of the A.R.M., 1946, which reads as follows:

'That the Representative Body is of opinion (1) that the Central Ethical Committee should have the exclusive power and duty to initiate action against any member who accepts an appointment that was the subject of an Important Notice at the time of its acceptance, (2) that the acceptance of a prohibited appointment shall be construed as *prima facie* evidence of an ethical offence justifying expulsion from the Association, (3) that the member concerned shall be afforded full opportunity to offer explanations to the Central Ethical Committee for his action or to present in argument any extenuating circumstances that appear to him to apply to the case, further, that the Council be requested to regard such action by the Central Ethical Committee as separate and apart from the investigations that are conducted under the existing Ethical Rules, and (4) that in respect of this new power vesting in the Central Ethical Committee, the Council be requested to prepare a report thereon together with Rules of Procedure for presentation to the next meeting of the Representative Body.'

The suggestion that the Central Ethical Committee should be empowered to initiate action in cases of the kind referred to in the above resolution is not new. In 1929 a Branch Council, having considered the conduct of a member who had accepted a public health appointment on terms inconsistent with the Association's policy, resolved to take no further action in the matter, with the result that the Representative Body in that year instructed the Council to consider the advisability of action being taken centrally when there was a *prima facie* case for expulsion and the local Division or Branch had failed to take disciplinary measures. The Council advised against this proposal and the A.R.M. in 1930 rejected an amendment "that in the opinion of the Representative Body the time has now come for the Council to take to itself power to deal with ethical cases which may not have been referred to it by Branches or Divisions."

In 1937 a letter was received from the Society of Medical Officers of Health which pointed out that members of the B.M.A. who accepted prohibited appointments in the public health field injured not so much the interests of local members of the Association as those of the public health service members in all parts of the country. The Society asked the Association "to consider so altering its constitution as to enable the cases of acceptance of public health appointments which have been the subject of warning notices in the *British Medical Journal* to be dealt with by a central committee of the

Association rather than 'local Divisions' The Society had expelled seven of its members who had applied for or accepted appointments not in conformity with the Askwith Memorandum of 1929, but although forty members of the B.M.A. had accepted such appointments, in none of these cases had the Division or Branch concerned made representations regarding expulsion, and the Council was precluded by the Articles of Association from taking any action in the absence of such representations.

In 1937 the Council did not see fit to recommend the adoption of the suggestion made by the Society of Medical Officers of Health. In the following year, however, the Central Ethical Committee reconsidered the position in relation to ethical cases generally and not merely cases of acceptance of prohibited public health appointments and the A.R.M. in 1938 approved a recommendation of the Council that the Articles should be altered by the deletion of the reference to a representation by a Division or Branch as an essential preliminary to the holding of a central inquiry with a view to expulsion. The following is an extract from the report made by the Council to the Representative Body in 1938:

The Council considers that this power is necessary to meet particular circumstances, as for example, in the event of an inactive Division or when complaint is made to the Association of conduct which offends the Association generally rather than any individual member or Division. In short, while leaving as at present any Division or Branch free to initiate and to conduct an inquiry into the conduct of any of its members with the right of such member if he so desires to appeal to the Council, the Council now proposes that it should be empowered to instruct the Central Ethical Committee to deal with complaints which either have not been considered by a Division or Branch or have been referred to the Central Ethical Committee by a Division or Branch without any local inquiry or judgment.

But although since 1938 the Central Ethical Committee has had power to initiate ethical inquiries, in practice the exercise of this power has been restricted by assurances given to the Representative Body that the Division would always be allowed to hold an inquiry locally if it so desired and that it was most unlikely that an inquiry would be initiated centrally in opposition to the wishes of the Division. So far as one particular type of ethical case is concerned the resolution of the A.R.M. 1946 alters this situation. It takes away from the Division the right to hold a local inquiry, and it relieves the Central Ethical Committee of the moral obligation to consult the wishes of the Division before deciding to initiate a central inquiry.

The Council welcomes this change of procedure. As the Central Ethical Committee is responsible for sanctioning the publication of an 'Important Notice' it thinks it right that the Committee should be responsible also for carrying out the logical continuation of that policy by holding an inquiry when the prohibition implied in the notice has been defied by a member. It agrees with the view expressed by the Representative Body that such cases are in a different category from those normally investigated by local Ethical Committees in which there is a personal issue between a complainant and a respondent. Acceptance of a prohibited appointment is an offence not against an individual but against the policy of the Association and it is unreasonable that the central authority which has issued the prohibition should find its future action inhibited by a single local Division, and equally unreasonable that two members guilty of precisely the same offence should receive different treatment according to the differing standards of the Divisions to which they happen to belong. It is only by the new procedure which the Representative Body has proposed that all cases of this kind can be investigated, as they should be investigated in a uniform way. Rules governing the conduct of this type of case are incorporated in the proposed new rules of the Central Ethical Committee referred to in the next paragraph of this report.

Rules of the Central Ethical Committee Relating to Complaints Regarding Professional Conduct

90 As has been stated above an alteration of the Articles of Association in 1938 had the effect of conferring on the Central Ethical Committee the power to initiate an inquiry and as a result of such an inquiry to recommend the expulsion of a

member whose conduct had not been considered by any local Division or Branch. But the A.R.M., 1938, was assured that this new power would not be used to interfere with the right of the Division to hold a local inquiry when it so desired. Anxious to keep faith with the Representative Body, the Central Ethical Committee proceeded to draft, for its own future guidance and that of its successors, rules of procedure defining the circumstances in which inquiries would be initiated centrally, and the procedure to be followed at such inquiries. This work was interrupted by the war but has lately been resumed and the Committee now thinks it desirable to extend the scope of the rules of procedure originally contemplated and to adopt a comprehensive set of rules comparable to those adopted by Divisions and Branches and governing all ethical inquiries conducted by the Committee, whether or not initiated by it. The rules drafted by the Committee, in close consultation with the solicitor, have been approved by the Council which recommends:

Recommendation That the Rules of the Central Ethical Committee relating to complaints regarding professional conduct (Appendix II) be approved.

Alteration of Division Ethical Rule 5 (Branch Rule 6)

94 Under Ethical Rule 5 of a Division (Rule 6 of a Branch) the Honorary Secretary of a Division (or Branch) is required to initiate ethical proceedings against a local member who has accepted an appointment in contravention of a Binding Resolution of the local unit of the Association. But such an appointment may also be the subject of an 'Important Notice' in the *British Medical Journal* in which case the initiation of ethical proceedings is now the exclusive duty of the Central Ethical Committee. It is therefore necessary to alter Rule 5 of a Division (Rule 6 of a Branch) in order to render it inoperative in the latter type of case. The Council recommends:

Recommendation That Ethical Rule 5 of a Division (Rule 6 of a Branch) be amended by the insertion (1) at the beginning of the Rule of the words

Subject as hereinafter provided

(2) at the end of the Rule of the words

Provided that no action shall be taken under this rule by the Honorary Secretary of the Division (Branch) where a member of the Association has accepted an appointment which, in addition to being held upon terms or conditions inconsistent with a Resolution of the Division (Branch), was the subject of an 'Important Notice' in the *British Medical Journal* at the time of its acceptance.

Family Planning

95 The Council has considered the activities of the Family Planning Association, a body conducting clinics throughout the country, and has made suggestions as to the manner in which these clinics should be conducted.

ORGANIZATION

Expenses of Members attending Meetings

96 The Annual Representative Meeting in 1946 passed the following resolutions:

70 Proposed by Leeds (J. A. L. Vaughan Jones) That Representatives, Members of Council, Members of Standing Committees or other Committees set up by the Council be paid a subsistence allowance of £1 ls per day or part of a day when attending the appropriate meetings of the Representative Body, the Council, the Standing and other Committees.

71 Whereupon an Amendment by Eastbourne (P. W. Mathew) That the expense of payment of representatives and others attending meetings of the B.M.A. would place such a large strain on the resources of the central funds of the B.M.A. that these motions should be withdrawn and that Divisions should by means of a local levy individually defray the expenses of their representatives.

With the permission of the meeting the words 'if they so desire' were added to the Amendment.

The Amendment was LOST (by 98 votes to 84).

72 Whereupon an Amendment by J. A. Ireland seconded by J. Griffith Jones That payment of expenses be made

- (a) as to attendance at representative meetings, by local levy
- (b) as to attendance at committees, from central funds

73 Whereupon it was proposed by the Treasurer, seconded by H S Howie Wood, and

Resolved That this matter be referred to the Council for inquiry

The Council has accordingly made inquiry into the matter and submits the following report

The Present Position

Members of the Representative Body, Council, and central Committees when attending meetings are reimbursed the amount of their first-class rail fares (including sleepers where necessary) Allowances are also paid as follows

Chairman of Council	{£1 1s per day, plus £1 1s if
Chairman of RB	{stay overnight is necessary
Members of Office Committee	5 guineas per attendance
Members of Publishing Subcommittee	5 guineas per attendance

The General Principle

The Association owes a great debt to the devotion and self sacrifice of individual members, and without their unselfish labours it could not have attained its present standing as the representative body of the profession Election by colleagues as a member of the Representative Body or the Council or one of the central Standing Committees is regarded as an honour and an expression of esteem and confidence In accepting office the member knows that on his side some sacrifice of his time and leisure will be involved, and that that is his contribution to the corporate work of his Association He gains a great deal from his contact with members from other areas, from the open discussions on topics of current interest, and from the opportunities afforded by visits to London of meeting the headquarters staff He finds his knowledge increased his outlook and point of view broadened, and his value to his constituency enhanced Most members would agree that these more intangible results of their tenure of office are a not unfair return for the financial outlay involved

The reasons, however, which have been advanced for making additional payments to members attending these meetings are as follows

1 The desire to ensure that members of the Association who attend the A R M and Council and Committee meetings shall not suffer financially by absence away from home on Association business Provincial representatives to the A R M may have to spend up to four or five days away from home and members of Council and Committees up to two nights for a whole day meeting in London The payment of the railway fare of members coming from Scotland or the provinces has always been considered a necessary reimbursement, as the burden might prevent adequate attendance by country members but the cost of meals and any necessary hotel accommodation has been borne by the member

2 The feeling that the non payment of subsistence allowances from central funds discourages younger members from accepting service as representatives and from seeking nomination as members of Council There is the implied criticism that the membership of the Representative Body and Council tends to consist of the older, retired, or semi retired members In order, therefore, to throw light on the validity of this criticism the average age of members of the Association attending Representative Meetings and Council has been assessed (basing the average age on qualification as 24) and has been found to be 51.3 (Rep Body 47.9, Council 54.8)

In addition a representative selection of Standing Committees has been assessed on this basis and reveals the following (the figures in parentheses representing the average age less the ex-officio officers)

Consultants and Specialists Committee	52.6 (50.4)
General Practice Committee	55.7 (51.2)
Hospitals Committee	56.0 (51.0)
Insurance Acts Committee	53.6 (51.6)
Organization Committee	60.4 (53.2)
Public Health Committee	61.8 (58.5)

3 It has also been said that the holding of Representative Meetings during the holiday period is a deterrent to the younger man who prefers to spend his holiday with his family rather than sacrifice it to attend B M A meetings

4 The unfairness that the financial loss in attending meetings is very much heavier for a provincial member than for a London member

5 The fear that this unfairness leads to the appointment of an undue proportion of London members on central Committees

6 The anomaly that whilst payment is made for a bed in a train no payment is made for a bed in a hotel

7 The growing complexity of the work demanding more thought and time, and the growing complexity of medical practice itself

Do these reasons make it desirable to establish the principle of payment of subsistence allowances to members attending meetings? The point has been made that the principle has already been conceded by the Council in deciding to pay subsistence allowances to the Chairman of Council and the Chairman of the Representative Body These two officers are required to spend an exceptional amount of time on important day to day Association business, both in attending meetings and in travelling to and from Headquarters Bearing this in mind the Council felt that it would be unreasonable to expect them to shoulder these responsibilities and to pay their own out of pocket expenses

The Legal and Financial Aspect

Apart from the principle there are financial considerations which in the view of the Council ought to receive due weight

Payments made from the Association's funds are subject to the conditions on which the licence is granted by the Board of Trade in pursuance of Section 23 of the Companies Act, 1867 These provide that the income and property of the Association shall be applied solely towards the promotion of the objects of the Association and no portion thereof may be paid or transferred directly or indirectly by way of dividend or bonus or otherwise, by way of profit provided that nothing shall prevent the payment in good faith of remuneration to any officers or servants of the Association or to any member or other person in return for any services actually rendered to the Association (Paragraph 4 of the Memorandum of Association)

The Articles of the Association (Article 49) provide for the payment of expenses to members attending meetings of the Representative Body, Council, and Committees, the term "expenses" being defined in the By laws (By law 86) as first class travelling expenses

Any departure from the existing practice would, therefore necessitate alteration of the By-laws

The proposition of Leeds at the Annual Representative Meeting in 1946 envisaged a payment of £1 1s per day or part of a day It is felt that the Representative Body would wish to have an estimate of additional annual expenses if payment were made on this basis, it is also felt that an alternative method of payment should be considered The cost to the Association of paying first-class return railway fares and subsistence for each meeting on the basis of £1 1s per day or part of a day has, therefore, been calculated in respect of a representative selection of Standing Committees (System A) In addition payment on the basis of the subsistence allowances paid to members of the Civil Service (namely 7s 6d for absence of under 10 hours and 25s for absence over 10 hours) has been calculated (System B)

This reveals the following

SYSTEM A		
Committee	Total cost for each meeting	Average per member
Organization Committee	£11 11s 0d	£1 1s 0d
Hospitals Committee	£13 13s 0d	£1 1s 0d
Insurance Acts Committee	£45 3s 0d	£1 1s 0d

In addition to the £1 1s a day payment each member would receive (as at present) first class return railway fare plus sleeper where needed The total cost in respect of subsistence allowances for all meetings for the complete session would be approximately £5,500

SYSTEM B		
Committee	Total cost for each meeting based on C S Scale	Average per member
Organization Committee	£11 17s 6d	£1 1s 8d
Hospitals Committee	£14 0s 0d	£1 1s 6d
Insurance Acts Committee	£49 7s 6d	£1 2s 10d

For the purpose of the above figures absence from home over 10 hours has been assessed as absence from home for one night—thus the highest Civil Service daily subsistence allowance of 25s has been allowed. Under this system first class return railway fares are refunded. Payment is also made for sleepers if used, but in these cases the subsistence allowance is reduced by one third. The total cost to the Association under System B would be approximately £5 700.

Local Levy

During the discussion at the Annual Representative Meeting in 1946 it was suggested that the payment of subsistence allowances would place a large strain on central funds and that one method of meeting this demand would be for the Divisions to defray expenses by means of a local levy. The Council has always encouraged Divisions to establish voluntary funds from which expenditure which cannot be met from ordinary Division or Branch funds can be defrayed, but so far less than 10 per cent have done so, and less than half this number have used these funds to reimburse, in part, their representatives for attendance at Representative Meetings. The institution of voluntary funds for this purpose does, however raise certain anomalies. Thus, a Division in the North of England or Scotland with a relatively small membership would need to impose a very high levy in order to pay the out of pocket expenses of a representative attending the Representative Meeting as against the case of a Division in the home counties area. There would also be the problem of numerical distribution, it would be difficult to assess the amount of the levy where a constituency comprises more than one Division each with varying memberships.

Proposals of the Organizing Committee and the Council's Decision

The Organization Committee in submitting the above report to the Council proposed that the Council should recommend to the Representative Body that, in addition to first class return railway fares (including sleepers) payment of subsistence allowances be made to members of the Association attending centrally arranged meetings on the following basis:

For absence from home over 8 hours	10s
Where stay overnight is necessary, an additional	£1 0s
Where a sleeper is claimed the overnight payment to be reduced to	10s

Where attendance on consecutive days does not necessitate the use of hotel accommodation payment on the day basis only to be made.

Payment on this scale would mean an annual charge to the Association of approximately £4 750.

The Council is equally divided upon this proposal.

Regional Organization

97 The Council has considered the following Minute 96 of the A R M, 1946:

96 *Resolved* That in view of the possibility of the National Health Service Bill in its final form being unacceptable to the profession this meeting is of opinion that the Council should take further steps to arrange for local organizers preferably medical on a regional basis.

In pursuance of this resolution a plan on the lines of a statement made to the A R M in July 1946 has been evolved for making the services of the central medical staff available to Divisions and Branches. Each of the five Assistant Secretaries has been allotted one fifth of the country, and approximately one third of his or her time is placed at the disposal of the local units. Two additional assistant secretaries are being appointed making seven assistants eventually available for this part time work. This is a first step towards the desired object and the Council is of the opinion that Divisions should have some practical experience of this method and assess its value to them before further arrangements are made to give detailed effect to Minute 96.

The Council points out that, even if the appointment of locally resident Regional Secretaries should prove to be necessary and desirable some time must elapse before this can be

achieved, there are difficulties of accommodation, selection of appropriate centres for each region, etc., which are unlikely to be overcome within a year. Further, the introduction of a National Health Service will raise problems relating to the structure of the Association, and a recasting of the whole of its central and local machinery may be needed.

The Council has therefore put the present plan into operation as a temporary measure, and it will review the whole position at the beginning of the next session in the light of the experience gained.

Proposed Regional Councils within the Association

98 Consequent upon the setting up of Regional Hospital Boards under the National Health Service Act, the Council is considering the establishment within the framework of the Association of regional councils for the purpose of representing the views of the profession in the region in relation to the activities of the Boards. The areas of existing Branches and Divisions are such that it would be impossible to establish suitable regional bodies merely by linking together existing units, and the Council is considering the constitution of the proposed regional councils with a view to securing both election on a geographical basis and representation of the professional interests concerned. This matter will be the subject for a further report by the Council.

Medical Association of South Africa

99 The final agreement for affiliation between the Association and the Medical Association of South Africa has now been completed. The Council is also pleased to report that 942 of the 2,580 members of the MASA removed from the list of members as a result of the affiliation have rejoined the Association as 'unattached members'.

Representation of Divisions and Branches in Representative Body, 1947-8

100 The Council has decided that the grouping for election of Representatives to the Representative Body, 1947-8, shall be on the same lines as for 1946-7.

The Honorary Secretary

101 The essential link between the Council and individual members is the Division Secretary. Upon him Head Office relies to a very great extent both for information on local happenings and for assistance in carrying out the Association's policy. Without the help of the Division Secretaries, the Association could not function as an efficient organization, and the Council is very conscious of the debt the Association owes to them.

Some Honorary Secretaries devote many years of enthusiastic and loyal work in the service of the Association, and during the past year the Council has conveyed its thanks to ten Honorary Division and Branch Secretaries who have resigned office after holding it continuously for periods of from 18 to 26 years.

The Association and Medical Students

102 The Council is in close touch with the British Medical Students' Association with a view to stimulating the interest of medical students in the work of the Association and attracting them to its membership when they qualify. It believes that the younger members of the profession can make useful contributions to the formulation of professional policy and that they should be encouraged to regard joining the Association as an essential part of their entry to their professional career. The Council has set aside the sum of £300 to be awarded to medical students in the form of essay prizes, 6 to the value of £25 each to be awarded on a national basis, and a larger number of small prizes on a regional basis. In this way the Council hopes that the proposal will make the widest appeal to medical students.

The Council has also decided to provide facilities for the giving of BMA Lectures to medical students, on the lines of the present arrangements for Divisions and Branches.

In addition, the Council has extended the reduced subscription to the *British Medical Journal* of 10s 6d per annum to final-year medical students to include all those who have begun their clinical studies.

Amendments of Schedule to the By-laws

103 The Council is of opinion that there should be a liaison between the Journal and Science Committees and between the Organization and Dominions Committees by an interchange of members. The Council also considers that the name of the Naval and Military Committee should be changed to Armed Forces Committee.

Recommendation That the schedule to the By-laws be amended (i) by inserting in the column headed 'otherwise appointed' in the case of the Journal Committee the words 'I by the Science Committee' in the case of the Science Committee the words 'I by the Journal Committee', in the case of the Organization Committee the words 'I by the Dominions Committee', and in the case of the Dominions Committee the words 'I by the Organization Committee'.

(ii) by substituting in the column headed 'Name of Committee' for the words 'Naval and Military', the words 'Armed Forces'.

SCIENCE

Association Prizes

N Bishop Harman Prize

104 The Council has pleasure in reporting that under the will of the late Mr N Bishop Harman, the Association has received a bequest of £1,000, free of duty, for the increase of the Clinical Prize for Research in Consulting Practice, initiated by Mr Harman in 1939. The capital fund is now, therefore, £2,000 and the value of the Prize which is to be offered biennially, will be approximately £100. Owing to the outbreak of the war no award has yet been made, and the Prize will be open for competition for the first time during 1947. It is proposed to alternate this competition with that for the Katherine Bishop Harman Prize.

Sir Charles Hastings Clinical Prize

This Prize, which has for its object the promotion of systematic observation research and record in general practice was again open for competition during 1946 for the first time since the outbreak of the war. 15 essays have been received and in view of the lapse of time since the Prize was awarded and having regard to the high standard of the essays submitted, the Council has decided to make the award to two competitors, namely Frances Charlotte Naish, MB BCh of York, for her clinical study on 'Breast Feeding—A Guide to the Natural Feeding of Infants' and Henry Eric Wilkie Robertson, MA, MD of Christchurch New Zealand, for his clinical study entitled 'The Response of Lassitude, Coldness and Loss of Hair, following Pregnancy, to Treatment with Thyroid Extract, in Christchurch, New Zealand'.

Special letters of commendation have been sent to A N T Aikman, BSc, MB, BCh, Melton Mowbray, 'Pneumokoinosis in a Woollen Mill Operative', C Grantham Hill OBE, MB, FRCS Beccles, 'Midwifery in General Practice', D C Harris MB BS, Oxford, 'Minor or Masked Hypothyroidism', D R Snellgrove PhD MSc, MRCS LRCP, 'A Statistical Survey of the Work Performed and Type of Case met with in a Busy Mixed Practice over a Period of 3 Years'.

The Council has expressed its cordial thanks to Dr R G Gordon and Dr J C Matthews, who examined the essays submitted for the Prize.

Katherine Bishop Harman Prize

This Prize normally awarded biennially and which has for its purpose the encouragement of study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing was again open for competition in 1946. The Prize has been awarded to Ernest Rohan Williams MD FRCP FFR DMRE of London, for his essay entitled 'The Contribution of Radiology to the Diagnosis and Management of Obstetric Disproportion'. Letters of commendation have been sent to Cecil Mary Dnlihen MB ChB DCH, of Edinburgh ('Prematurity, Stillbirths, and Neonatal Deaths') and to Archibald Ian Stewart Macpherson MB ChB FRCS Ed of Edinburgh ('The Aetiology of Hypoproteinaemia and the Haemorrhagic Diatheses of the Newborn').

The Council has expressed its appreciation of the services rendered by Prof F J Browne and Prof James Young in examining and reporting upon the essays submitted.

Middlemore Prize

This Prize which consists of a Certificate and a cheque for £50 is awarded triennially for the best essay or work on any subject selected by the Council in any department of Ophthalmic Medicine or Surgery. During 1946 the Prize has been open for competition for the best essay on 'The Aetiology and Treatment of Chronic Endocyclitis'.

Two essays only were submitted, and in view of the fact that neither essay contained any record of original work, the Council does not propose to award the Prize in 1947.

Research Scholarships

When the practice of awarding Research Scholarships was resumed in 1946, it was decided, as a temporary measure, to restrict the tenure of the scholarships to a period of nine months in the first instance. Experience has shown, however, that this does not give the scholar sufficient time in which to complete his work, and the Council proposes, from Oct 1 next, to revert to the normal pre-war custom of awarding the scholarships for a period of twelve months to coincide with the academic year.

In reaching this decision the Council has given consideration to the amount of the present awards and to the question whether a smaller number of full-time scholarships of a higher monetary value would not serve a more useful purpose. In view, however, of the increasing number of junior appointments available under the aegis of the Ministry of Health, it is felt that the financial aid offered by the scholarships still provides a valuable means whereby, young practitioners interested in research but employed on comparatively low salaries may supplement their income. The Council accordingly recommends no change at present in the value of the scholarships.

The following scholarships have been awarded tenable for the first nine months of 1947.

Ernest Hart Memorial Scholarship W G Cross BDS MB, BS, MRCS, LRCP, LDS, RCS, London

Walter Dixon Memorial Scholarship R E Moore, MB, BS MRCS, LRCP, London

Ordinary Research Scholarships J B Brierley, MB, ChB Bristol; Emilie E Guthmann, BSc, MB, ChB, MRCP, London; M Anderson, MB, BS, MD, MRCP, Gateshead; Mary Savory, MRCS, LRCP, MB, BCh, BA, FRCS, London

Library

105 The use made by members of the facilities of the Library has shown a considerable increase since the end of the war, and the number of members using the Library for study purposes has been so great on occasions, particularly during the winter months, that it is becoming increasingly difficult to provide adequate seating accommodation. The number of readers during 1946 was 28,594, as against 25,297 in 1938, and 18,203 in 1945. The number of books borrowed in 1946 was 19,954, an increase of 2,402 over 1938.

The number of periodicals received from the Abstracting Service will undoubtedly prove a great asset to the Library but in view of the limitations of the present accommodation temporary measures have had to be taken to provide additional storage and display facilities. The Council looks forward to the vacation of the Garden Court Wing by the University of London and the re-housing of the Library in that Wing.

During the year 235 books and journals have been presented to the Library and the Council extends its thanks to the donors.

The Council has decided to extend all the privileges of the Library to members of the Canadian and South African Medical Associations visiting the United Kingdom.

BMA Lectures

106 The Council extends its thanks to the following practitioners who have given BMA Lectures during the period from April 1 1946 to Feb 28, 1947: Dr G Bourne, Prof D Dunlop, Lady Florey, Dr R Forbes, Mr D J Guthrie, Dr T Hunt, Prof C F W Illingworth, Dr G D Kersley, Mr C E Naunton Morgan, Dr A L P Peckey, Prof R Platt, Mr R M Titmuss, Dr G A Watkins, Mr D G Wilson, Clvnc.

Divisions and Branches are reminded that they may have one BMA Lecture during the course of a year. The lecturers are nominated by the Division or Branch and the expenses of the lecturer are defrayed by the Council from central funds.

Films

107 The Council has appointed a special committee to inquire into the scope and use of films for postgraduate and undergraduate medical education. The Council hopes to submit a report on this subject in its Supplementary Report.

Postgraduate Study for General Practitioners

108 The Council has given consideration to the following Minute 130 of the Representative Body 1946

That this meeting wishes to emphasize (1) the crying need of general practitioners for postgraduate study to keep abreast of the rapid advances in diagnosis and treatment, all the more so as the opportunities were few and far between during the war (2) that refresher courses should be made available for general practitioners at recognized teaching hospitals and they should be facilitated and encouraged to attend them.

Information has been sought from honorary secretaries of Divisions, secretaries of local medical and clinical societies, and from deans and postgraduate deans of medical schools, and it is apparent that there has been, since the end of the war, a steady development in the reintroduction of facilities for postgraduate study for general practitioners. Refresher courses for ex-Service and insurance practitioners are being provided at many of the university centres throughout the country and in addition a number of protracted courses and week-end courses are now being held and planned. Sunday morning and other periodic ward rounds are held at a number of teaching hospitals and the clinical meetings of Divisions and Branches and lectures and demonstrations arranged by local clinical societies which are, for the most part, designed to meet the need of the local profession make a valuable contribution towards providing the general practitioner with an opportunity of keeping abreast of modern methods of diagnosis and treatment.

The Council is of the opinion therefore that although in most areas the means of obtaining regular postgraduate education is available for the general practitioner it is agreed that the present facilities should be greatly extended, that particular attention should be paid to the areas furthest from teaching centres and that co-ordination between the various bodies providing postgraduate education is urgently needed.

It is felt that intensive refresher courses at intervals of three years or so valuable though they may be do not meet the need of the general practitioner for continuous postgraduate education and they should be regarded only as a part of a general scheme. The Council considers that the holding of regular clinical meetings of the profession at the local hospital is one of the most valuable methods of promoting postgraduate education and should be adopted in every area where there is a hospital with upwards of 200 beds. In the area furthest removed from teaching centres when facilities are most urgently needed it is suggested that instruction should be in the hands of the local consulting staff of the hospital with the aid of visiting teachers. In this way the local 200 bed hospital would become the centre of clinical instruction.

After a careful review of the whole problem, therefore the view of the Council is that postgraduate education should be arranged at a regional level and that a committee should be established in each region for the purpose of co-ordinating and promoting postgraduate study. Such a committee might consist of representatives from the universities, the staffs of local hospitals, local medical societies and the Divisions or Branches of the Association. Similar committees or sub-committees should be appointed within the regions at the level of area hospitals with not less than 200 beds.

GENERAL MEDICAL COUNCIL

Draft Medical Bill

109 In accordance with Minute 53 of the A.R.M. 1945 the Council appointed a special Committee to review the working of the Medical Acts with special reference to the composition, functions and procedure of the General Medical Council. The same subject has been considered concurrently by the GMC itself which has submitted to the Ministry of

Health a draft Bill for the amendment of the Medical Acts in certain respects and by the defence societies, which are mainly concerned with penal procedure.

It is understood that the Minister of Health proposes to introduce, as soon as Parliamentary time permits, a short amending Bill to give effect to the recommendation of the Inter-Departmental Committee on Medical Schools for the requirement of resident hospital appointments before registration and to certain other amendments which are unlikely to arouse controversy. The Council has therefore prepared a statement of its views on such modification of the Medical Acts as it considers to be urgently desirable and such points as practical experience has shown could now conveniently be introduced into the Act or Regulations under it. In order that the profession may present to the Ministry of Health as great a degree of unanimity as possible, conferences have been held with representatives of the General Medical Council and of the defence societies. Many of the original differences of opinion have been overcome by these conferences, but there still remain a few fundamental points of disagreement which must await resolution by the Minister of Health or during the passage of the Bill.

The statement which the Council has submitted to the Ministry of Health of its views on such revision of the composition, functions and procedure of the General Medical Council as might be undertaken forthwith in a short amending Bill is as follows.

1 Penal Procedure

1 Section 29 of the Medical Act of 1858 should be amended to read as follows

29 (i) If any registered medical practitioner shall be convicted in England or Ireland of any felony or misdemeanour or in Scotland of any crime or offence and is judged by the General Medical Council after due consideration to have been guilty of infamous conduct in any professional respect the Council may, if it sees fit, direct the Registrar to erase the name of such medical practitioner from the Register.

(ii) If any registered medical practitioner is judged by the General Medical Council, after due inquiry into any complaint received and supported by affidavit or affidavits, to be guilty of infamous conduct in any professional respect, such offence not amounting to a felony or misdemeanour, the Council may, if it sees fit, direct the Registrar to erase the name of such medical practitioner from the Register.

The amendment means that in the case of an offence which if established, would constitute a felony or misdemeanour, the Council should not make any investigation unless and until the offender has been tried in a court of law and that evidence of professional misconduct emerging from a trial for a felony or misdemeanour should be capable of being made the subject of complaint to the Council.

2 The General Medical Council should, by Statute, be empowered and required to establish two distinct and separate Committees to be known as (a) the Penal Cases Committee, and (b) the Discipline Committee.

No member of the Penal Cases Committee should be permitted to sit as a member of the Discipline Committee hearing any case which had appeared before the Penal Cases Committee at which he was present as a member.

3 Twenty members of the GMC should be appointed to be a Discipline Committee of which not more than twelve and not less than seven members should be appointed to hear any particular case. The Committee should sit with a legal assessor. If any member of the Discipline Committee engaged in the hearing of a case shall absent himself from any part of the proceedings he shall take no further part in the hearing of such case. If for any reason the numbers of the Committee be reduced below seven the hearing of such case shall be abandoned and if further proceedings be directed by the General Medical Council they shall be commenced *de novo*.

4 A decision of the Discipline Committee to erase the name of a practitioner from the Medical Register should not be valid unless it is supported by a vote of not less than two thirds of those members present.

5 It is undesirable that the Council's own solicitor should present a complainant's case either by himself or through Counsel.

6 If a practitioner is accused of an offence for the investigation of which there exists machinery under the National Health Service Act or other Act of Parliament, that machinery should be fully used before a complaint is submitted to the Council.

It does not necessarily follow that if, after inquiry through the official machinery, the practitioner's name is removed from the National Health Service or other special register, the Council should remove his name from the Medical Register.

7 The Council should not institute any inquiry without the receipt of a formal complaint except in matters arising out of the findings of a court of law or a legally constituted tribunal.

8 The attendance of witnesses and the production of documents before the Discipline Committee should be enforceable by *subpoena*.

9 All oral evidence before the Discipline Committee should be given on oath, save for good and sufficient reason, except evidence as to character, which may be given in writing.

10 There should be a right of appeal to the High Court on points of fact or of law against a decision of the GMC to remove a practitioner's name from the Medical Register.

11 In the event of an appeal any Order for erasure should be suspended until after the disposal of the appeal, subject to the appeal being entered within 21 days from the date of the Order.

12 The Discipline Committee should be empowered to award costs against a Complainant or Respondent and machinery should be established for taxing the costs.

13 The appropriate provision of the Medical Act should be amended to permit of the imposition of a maximum penalty of £500 and the alternative of a term of imprisonment for persons convicted of falsely holding themselves out to be registered medical practitioners.

14 Every complaint made to the Council should be supported by an affidavit or statutory declaration setting out the material facts.

15 A copy of the affidavit or statutory declaration should be sent to the practitioner concerned, and he should be allowed ample time to prepare his explanation or defence.

16 Provision should be made by regulation to enable applications for postponement of inquiries by the Discipline Committee to be made to the President and to be dealt with at his discretion.

17 Each party should furnish to the other, not later than 10 days before the hearing of the case, a list of documents on which they propose to rely.

18 Notice to produce and admit should be permitted.

19 The parties should be at liberty to ask the Discipline Committee to call a witness whose attendance is desired.

20 Only those documents which are agreed by the parties and such others as are proved in evidence should be placed before the Discipline Committee.

21 If any points of law be raised by, or on behalf of either party or by the Discipline Committee, the Legal Assessor should give his opinion upon them in the presence of both parties if present at the inquiry, and of their legal representatives if any.

22 An applicant for the restoration of his name to the Medical Register after penal erasure should be permitted to present his application personally and to make a personal declaration.

(Note—It is considered that the substance of paragraphs 1–13 should be included in the Act while paragraphs 14–22 could be made the subject of Regulations.)

II Direct Representatives

23 In order to provide a more suitable proportion of Direct Representatives on the GMC and also to ensure that a sufficient number of members with particular knowledge of general practice problems shall be available for the two disciplinary committees it is desirable that the number of Direct Representatives to the GMC be increased from seven to twelve, namely seven for England, one for Wales, two for Scotland and two for Ireland (one for Northern Ireland and one for Eire).

III Registration of Specialists

24 It is both undesirable and unnecessary at the present time to establish a statutory list of consultants and specialists.

IV Visitation of Medical Schools

25 It is desirable that visitors should be appointed by the GMC to visit medical schools.

Women Representatives

110 The Council has expressed its agreement with the principle that one of the Direct Representatives of the profession on the GMC should be a woman practitioner. It has inquired whether the Medical Women's Federation would prefer that steps be taken to recommend statutory provision for one of the Direct Representatives to be a woman or that the BMA should, so far as possible, ensure that at least one woman is included among the candidates selected for its support.

The Federation has replied that it prefers the latter alternative. The Council is therefore modifying its procedure for the selection of candidates in the election of Direct Representatives for England and Wales so as to ensure that support is given to a woman candidate.

PUBLIC RELATIONS

The Plebiscite and After

111 During the passage of the National Health Service Bill through Parliament the Council concentrated on stressing the reasons for the profession's objections to certain parts of the Bill and on the efforts to secure amendments.

In September, 1946, Mr A W Haslett, Public Relations Officer to the Association, resigned. Mr John Pringle was appointed to succeed him, taking up his duties in November.

Early in November the National Health Service Bill passed into law and the Association took its plebiscite of the profession on whether it was desired to negotiate with the Government on Regulations. Full publicity was arranged in the Press and on the wireless about the plebiscite and considerable public interest was aroused. As soon as the results of the plebiscite had been discussed by the Council a Press Conference was held to inform the Press of the Council's decision to recommend the Representative Body not to negotiate. This decision was on the whole unfavourably received by the Press. When the correspondence between the Royal Colleges and Mr Bevan was published, nearly all the Press welcomed Mr Bevan's letter as a conciliatory move which ought to be reciprocated by the profession. The Council's further resolution, confirmed by the Representative Body, to hold discussions with the Minister provided the possibility of further legislation was not excluded was well received by the Press.

The Council's protest against the action of the Minister of Food in blaming the medical profession for improper certification in respect of the supply of milk for invalids was widely publicized in the Press. Public sympathy was also secured in the publicity given to the overriding by the Ministry of Food of doctors' prescriptions of extra rations for certain categories of invalids. On Feb 8, 1947, the Minister of Food announced that 'a more lenient view' could in future be taken of individual applications for extra rations.

The Council regards the present stage of discussions with the Minister as an interim period unsuitable for intensive medico-political publicity. The Public Relations Officer has been instructed to develop long term plans for encouraging a better understanding by the Press and the Public of the work of the profession. To this end he will work in close co-operation with Divisions and endeavour to stimulate greater interest and activity in public relations work. It is planned to hold a series of local Public Relations Conferences to which groups of Division Public Relations secretaries will be invited.

Information Service at BMA House

112 The Council has decided to establish at BMA House an extensive Information Service primarily for the use of the Press, though it will also be used internally by the various departments.

Anginal Paine

In view of the now generally accepted theory that the pain of Angina Pectoris is due to myocardial anoxaemia a potent coronary vasodilator such as Cardophylin, may be of value in relieving the anoxaemia when this is due to an inadequate blood supply to the myocardium especially where coronary constriction is the main factor in interfering with the blood supply

DIGOXIN 'B.W. & CO.'

Digoxin B W & Co., being a single pure glycoside of constant composition and activity offers an unsurpassed degree of precision in digitalis therapy. Its rapidity of absorption and excretion, and the fact that it can be injected intravenously if necessary, are additional features of great importance.

The dosage of Digoxin B W & Co. is computed in milligrammes not units.

An Effective Analgesic

WHILE modern chemical research has evolved many and diverse analgesics the popularity of acetylsalicylic acid and its reputation for effectiveness remain. Nevertheless some physicians have hesitated to employ it owing to its tendency in certain conditions to irritate the stomach.

In Alasil, however, the desirable therapeutic effects of acetylsalicylic acid are maintained by the addition of Calcium Citrate, Calcium Aluminate, and Calcium Hydroxide. Thus Alasil helps to solve the problem of administering acetylsalicylic acid in an effective form even to patients with sensitive stomachs.

The advantages of Alasil have been well proved in practice. Experience shows that it can be prescribed with safety to patients of all ages.

Each tablet contains 5 grs. Acetylsalicylic acid, 6 grs. Alcohol (Cellulose), 1 gr. Calcium Hydroxide, and 1 gr. Dihydrate Calcium Phosphate.

LIVOGEN

Trade Mark

Following the cancellation of the Liver Extract (Regulation of Use) Order, 1945 (b), Livogen is now available for general medicinal use.

Livogen contains, in addition to fifty per cent of liquid extract of liver B P, extract of yeast, vitamin B₁ and nicotinic acid.

Livogen is of remarkable value in the treatment of anæmias, in the prevention of polyneuritis induced by gastric abnormalities and of the polyneuritis of pregnancy and of alcoholism. It is prescribed also in the various degrees of lassitude and debility characteristic of convalescence following severe illness. Full particulars are available on request.

in the office. The Public Relations Officer has drawn up plans for the organization of this service. These plans have been approved by the Council and it is expected that the service will be functioning, if initially on a modest scale, by the autumn of 1947.

In order that the position of the Association as a scientific body should be more fully recognized by the Press and the Public, the Council has decided to institute a series of lectures to be given in this country by distinguished medical men from abroad specially invited here by the Association. The Public Relations Officer will draw up a scheme. Valuable suggestions have already been received from the Science and International Relations Committees.

The Public Relations Officer is also exploring the possibility that the Association might organize an international medical Summer School in this country. As a further means of enhancing the Association's scientific prestige and of increasing public good will for the profession the Council has considered the following Minute 14 of the Annual Representative Meeting, 1946. *Resolved* That the publication entitled *Charter for Health* should be subsidized by the B.M.A. and sold to the public at a considerably reduced price. Because of paper shortage and other difficulties in the publishing trade neither the original publishers of *Charter for Health* nor other publishers of whom inquiries have been made have been able to undertake republication. Further attempts are however being made to secure publication of a cheaper edition.

INTERNATIONAL RELATIONS

World Medical Association

113 In its last Annual Report the Council stated that it was arranging in co-operation with the Association Professionnelle Internationale des Médecins an international medical conference to discuss the means of bringing about closer ties between the national medical associations in the different countries. A very successful conference at which 32 countries were represented, was held at B.M.A. House on Sept. 25 to 27, 1946, under the Chairmanship of the President, Sir Hugh Lett and at that conference a World Medical Association was formed with the following provisional objects:

- (i) To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available in order to assist all peoples of the world to attain the highest possible level of health.
- (ii) To study the professional problems which confront the medical profession in their different countries.
- (iii) To organize an exchange of information on matters of interest to the medical profession.
- (iv) To establish relations with and to present the views of the medical profession to the World Health Organization, Unesco and other appropriate bodies.

The members of the World Medical Association will be national medical associations.

Dr Charles Hill was appointed provisional Joint Secretary with Dr P. Cibrice of Paris. An Organizing Committee of nine members who included Dr J. A. Priddyham was appointed to prepare a draft Constitution and to proceed with the organization of the World Medical Association. The first annual meeting of the World Medical Association is to be held in Paris in September 1947.

The Council on behalf of the Association has accepted membership of the World Medical Association. So far the following countries have joined: Austria, Belgium, Canada, Denmark, France, Great Britain, Netherlands, Norway, Peru, Portugal, Switzerland and U.S.A.

B.M.A. Lectures Abroad

The Council decided in 1946 that the medical profession in many European countries, especially in those which had been occupied by the Germans, had lost touch with developments in medicine and surgery and that they were looking to Great Britain for help in filling the gap. To meet this demand for information the Council has set aside the sum of £10,000 for the years 1946-57 for the purpose of providing lectures by the B.M.A. and distinguished British practitioners in the profession in Europe. A special subcommittee

has been appointed to administer the scheme, in which close co-operation will be maintained with the Royal Colleges and the British Council.

The first B.M.A. Lecture abroad was given by Dr S. C. Dyke of Wolverhampton, in Czechoslovakia in November, 1946.

British Medical Literature in Europe

115 Another effect of the war was the suspension in Europe of the circulation of medical books and periodicals. European doctors are now looking to Great Britain not only to revive its pre-war export of books and periodicals but also to fill the place in the dissemination of knowledge formerly taken by Germany. The Association's new Abstracting Service will be a valuable help, and already a large number of B.M.A. publications are distributed, free of charge, to European countries through the British Council. The Journal Committee is exploring the possibility of distributing more through the Central Office of Information.

International Postgraduate Centres

116 A desire has been expressed in some foreign countries for the establishment in London of an international postgraduate centre consisting of a large general hospital and a school with laboratories and other facilities for teaching and research. It is suggested that such a centre would meet a strongly felt need in Europe, and that it could take the place filled by Vienna before the war. The matter is being discussed with the British Postgraduate Federation.

NAVAL AND MILITARY

Indian Medical Service

117 Representations have been made to the India Office emphasizing the importance of an early declaration of policy to allay the anxiety of officers in the Indian Medical Service regarding the future employment of or the compensatory terms to be granted to, officers of the Service consequent upon constitutional changes in India.

The India Office has been informed that while a number of officers employed in the Indian Medical Service would be prepared to accept transfer to the R.A.M.C., retaining their present rank and seniority, a number of officers who entered the Service with a view to civil employment are likely to find the prospect of further military service unacceptable. The Council is of the opinion that officers retiring from the Service should receive in addition to any gratuity ordinarily accruing to them, reasonable compensation for their long absence from civil practice and be given an opportunity of attending postgraduate courses before their retirement. It has asked the India Office to receive a deputation to discuss the matter and has received an assurance that consultations with the Association on questions of compensation and future employment of officers of the Indian Medical Service will be welcomed when the policy regarding the future of the Service is being determined.

Post-war Code of Pay—Encouragement and Reward of Specialization

118 Information has been received from the War Office regarding the regulations to be made for the encouragement and reward of specialization by Service medical officers. Under the regulations previously in force additional pay was granted in the Navy and the Army to medical officers with the necessary qualifications when filling specified specialist appointments, while in the R.A.F. a system of accelerated promotion was applied.

In the Army the grant of additional pay to a specialist medical officer, admissible only while he filled an established specialist appointment, has been abandoned in favour of a scale of qualification pay for subalterns, captains, majors and lieutenant-colonels. This pay will be drawn continuously by officers who possess the required qualifications regardless of the nature of their employment and irrespective of whether they are filling an established specialist post. The qualification standards will be such that the number of officers who attain them will be limited. In effect a medical officer who

by his qualifications and experience has been classified as a specialist will now receive qualification pay at the rate of 4s a day, which he will draw continuously until he is promoted above the rank of lieutenant colonel.

In the Navy and the R A F the existing systems are being retained. In the Navy, therefore, a specialist medical officer not above the rank of surgeon commander, will continue to be eligible for additional pay while he is actually filling a specialist appointment. The rate will be 5s a day. In the R A F officers who are recognized as specialists will receive a credit of two years seniority in the ranks of flight-lieutenant and squadron-leader. The standard required for the grading of an officer as a specialist will be the same in all three Services, and comparable limitation of numbers will apply.

The War Office has been asked for information as to the "qualification standards" to be attained by Service medical officers for the issue of specialist pay.

Demobilization

119 Council has considered the following Minute 190 of the Annual Representative Meeting, 1946

Min 190 Resolved: "That this meeting does not regard the release from the Services as satisfactory, and considers that establishments are overstaffed."

The Council is informed that while no complaints are being received about the rate of release of general duty medical officers, who are being released at a faster rate than officers of other arms of the Service, the release of specialists is particularly difficult. The Central Medical War Committee has made representations to the Government on the question of the over-staffing of Service hospital establishments, and this matter has been considered by the Medical Personnel Committee, which appointed three teams of two of its members to visit Service establishments in Germany, the Middle East, and India. Consideration of Minute 190 of the A R M has been deferred pending publication of the report of the Medical Personnel Committee.

Future Conscription

120 The Council has considered the application of the National Service Bill to the medical profession.

The Bill provides that all men between 18 and 26 years of age shall be liable to 18 months' full time military service (this may be amended to 12 months) to be followed by 5½ years part-time service during which they may have to undergo a total of 60 days' further training. The Bill does not specify whether doctors or intending doctors will be required to undergo their conscripted service as combatants in the ranks before qualification or as commissioned medical officers after qualification, and although postponement of service is referred to in Clause 17 the grounds are not defined, and an 8-year period of liability will leave the medical student uncertain as to when he will be required to serve.

Clause 9 of the Bill provides that registered medical practitioners undergoing training for the purpose of acquiring further qualifications or special experience may defer their conscripted service until attaining the age of 30.

After consideration, and having obtained the views of the British Medical Students Association, the Council has expressed the opinion

(1) That young men intending to enter the medical profession and within the age limits of conscription (18 to 26) should be given the option of completing their conscripted service before or after qualification, provided

(i) if they elect to be conscripted before qualification they be given the definite option of being called up on their eighteenth birthday,

(ii) if they elect to be conscripted after qualification they must continue to receive satisfactory reports from the Deans of their Medical Schools.

(2) That recruitment of specialists should be upon a voluntary rather than a conscript basis, terms of service being made sufficiently attractive to ensure an adequate supply of volunteers of specialist status.

The Council has approved the action taken by the Naval and Military Committee in sending to the medical members of both Houses of Parliament a statement outlining the Association's views.

SCOTLAND

121 Dr George McFart and Dr I D Grant were appointed Chairman and Deputy Chairman of the Scottish Committee for the session 1946-7.

Retirement of Scottish Secretary

122 The Council desires to put on record its cordial thanks to Dr Craig for his outstanding and devoted services to the Association as Scottish Secretary from 1931 until Sept 30, 1946, when he retired under the age limit. Scottish members of the Association and the Scottish Committee expressed their appreciation to Dr Craig at a farewell function held at the Scottish House on Oct 4, 1946 when he was presented with a cheque in token of their regard.

Interim Increase in Salaries of Medical Officers of Health

123 In collaboration with the Scottish Branch of the Society of Medical Officers of Health an endeavour is being made to secure interim increases in the Scottish scale of salaries of whole time medical officers of local authorities approved by the Representative Body in 1927, similar to those agreed in England and Wales in respect of the Askwith Memorandum. There is no arrangement with the Scottish Associations of Local Authorities similar to that which exists in England and consequently there is no agreed scale. Representations have, however, been made to the three Scottish Associations of Local Authorities, and it is hoped that the matter will be the subject of discussion at an early joint meeting.

Motherwell Town Council—"Closed Shop" Policy

124 The Motherwell Town Council has applied the "closed shop" policy to its whole time employees. It is not yet known whether the medical practitioners and nurses in the whole time employment of the town council will be included among the exceptions allowed in a resolution of the local authority. The situation is being closely watched, in collaboration with the Scottish Branch of the Royal College of Nursing, and appropriate action will be taken, pursuant to the policy of the Association, in the event of the position of medical officers and nurses being affected by the resolution of the town council.

Organization of Consultants and Specialists and Whole-time Members of Public Health Service in Scotland

125 Hitherto there has been no machinery in Scotland analogous to that which exists through the Central Consultants and Specialists and Public Health Committees for ascertaining the views of the members of the profession in Scotland employed in these two branches of medical work. In view of the approach of the National Health Service it is essential that such machinery should be available, and the Scottish Committee has therefore appointed (i) a Consultants and Specialists Subcommittee representative not only of the various specialties but also of the Royal Corporations and the Universities, (ii) a Public Health Subcommittee composed of representatives of the various types of Public Health Service (including Superintendents of Hospitals and the Mental Hospital Service) and representatives appointed by the Scottish Branch of the Society of Medical Officers of Health. These subcommittees have already proved exceedingly useful in the discussions on the relevant sections of the National Health Service (Scotland) Bill.

National Health Service (Scotland) Bill

126 The provisions of the Bill have been the subject of close scrutiny by the Scottish Committee, and its recommendations have been submitted to the Scottish Negotiating Committee, which has met the Secretary of State by deputation on two occasions. The Secretary of State was not prepared to make any concessions in respect of the basic principles adopted by the Association, but he made concessions in respect of other matters put forward by the Negotiating Committee and expressed his willingness to meet the Committee for further discussions. The views of the profession in Scotland have been presented to the Scottish Unionist Members of Parliament and Scottish Labour Group Members in an endeavour to secure

amendment of the Bill in accordance with the basic principles of the Association, during the Scottish Grand Committee stage which is now proceeding

Scheme for Loans for Purchase of Practices in Scotland

127 There have been legal difficulties associated with the advance of loans for the purchase of medical practices in Scotland and the subject has been fully examined in conjunction with officials of the Medical Insurance Agency. Insurance and finance experts have been consulted and several insurance companies have been approached with the result that the Medical Insurance Agency in Scotland is now able to arrange facilities similar to those available under the Agency's Practice Loan Scheme in England and Wales.

Linkson Committee with Scottish Branch of the Royal College of Nursing

128 A Linkson Committee with the Scottish Branch of the Royal College of Nursing has been established for the purpose of discussion of and co-operation in matters of mutual interest.

Annual Scottish Function

129 It is proposed in the future to hold under the joint auspices of the Scottish Committee and Insurance Acts Subcommittee (Scotland) an annual social function. Members will be entitled to bring guests and a number of official guests will be invited. It is felt that such a function could not fail to be of considerable propaganda value to the Association in Scotland.

WALES

130 The Welsh Committee met at Shrewsbury on Dec. 5 and reappointed Dr. H. R. Frederick as its Chairman. The Committee is anxious that its activities should be national in character and that every effort should be made to interest Branches and Divisions in Wales in its work in order that local problems and difficulties may be referred to the Committee for its consideration and where necessary support.

A new function devolved upon the Committee last month when it met to select the names of six Welsh practitioners from those nominated by Divisions in Wales as the Association's nominees for membership of the newly constituted Welsh Regional Hospital Board.

In this connexion the Committee has welcomed the announcement that Wales and Monmouthshire have been recognized as an autonomous region for the purpose of the National Health Service but considers that temporary and special arrangements are necessary in respect of areas more readily worked with university centres in England.

OVERSEAS BRANCHES

Colonial Advisory Medical Committee

131 As reported to the Representative Body in 1946 the Council suggested to the Colonial Office that the Association should be represented on the Central Advisory Medical Committee which advises the Secretary of State in the formulation of policy. The Secretary of State replied that apart from certain representatives of Government Departments or of quasi-official bodies appointments to the Committee are made in a personal capacity and not on the basis of representation of particular associations and moreover that the Committee does not normally concern itself with questions relating to terms of service in the Colonial Medical Service in which the Association would be particularly interested. The Secretary of State intimated, however, that he was anxious to continue to have the opportunity of considering suggestions or advice from the Association. In particular should the Advisory Committee be asked to advise on questions relating specifically to terms of service he would be glad to invite the Association to send a representative to the meeting to submit the Association's views.

The Secretary of State has been pressed to reconsider his decision and as a result he has indicated that if the Association could submit a list of persons who in his view are fitted by their experience to be of service to the Committee, he would be pleased to consider their names when making further

appointments to the Committee. The Council proposes to take advantage of this invitation.

Co-operation with the Dominions

132 The Council is anxious to establish a closer link with the profession in the Dominions, and it believes that this desire is shared by practitioners overseas. It has therefore appointed a special committee to consider and report upon the question of contacts and co-operation between the profession in the Dominions and in this country.

Ex-gratia Payments to Doctors Interned in Malaya

133 The Council reported to the Representative Body in 1946 the action which had been taken in an endeavour to secure more favourable treatment for a number of practitioners in private and estate practice in Malaya, who were mobilized in the Malayan Auxiliary Services and who were subsequently captured and interned by the Japanese. The initial offer indicated by the Colonial Office was to the effect that those members of the Civil Defence Services of Malaya and Hong Kong who were not eligible as Government servants or otherwise for accrued pay during internment might be granted ex-gratia payments equivalent to three months pay of their Civil Defence posts. In consequence of representations by the Council the Department next intimated that ex-gratia payments equivalent to accrued pay for the period of internment, at the rate appropriate to rank, might be granted subject to (i) a deduction of 10% (ii) a maximum of £1,500 in any one case (iii) deduction of payments already made. Further representations have been made to the Colonial Office and it is now understood that the 10% deduction (which was intended to represent local taxation to which the payments would normally have been subject) will be waived in respect of payments up to £1,250.

The Department, while acknowledging that the maximum of £1,500 was an arbitrary figure, maintained that no one who was temporarily employed in Government service on account of the emergency could reasonably expect to receive as an ex-gratia payment, a sum in excess of £1,500 in respect of the period of internment. The Colonial Office also drew attention to the fact that all internees were given free passages to their homes and those who wished to return to Malaya were being sent back without cost, that free medical and hospital treatment had been afforded and that internees were eligible for the benefits of the Personal Injuries Scheme operating in the United Kingdom.

The Council, while of the opinion that the terms offered are far from generous, feels that no useful purpose will be served by pursuing the matter further with the Colonial Office.

Salary Scales—East Africa

134 The Council has considered a complaint from one of the East African Branches regarding the salary scales of Medical Officers in the Colonial Medical Service. The Council is strongly of the opinion that the salaries of Medical Officers in East Africa are totally inadequate at the present time both in the light of the findings of the Spens Committee and as compared with the rates of remuneration now obtaining in the profession in the United Kingdom and that they are not such as to attract to the Colonial Service practitioners of the calibre required for the Service. The Council therefore proposes to make representations to this effect to the Colonial Office.

Opportunities in the Colonial Medical Service

135 As reported to the Representative Body in 1946 the Council has received a number of complaints from Overseas Branches that the statement appearing in advertisements of vacancies in the Colonial Medical Service, that the Service offered ample opportunities for work in special branches of medicine and surgery in Public Health and Medical Research, was misleading as, in fact, few such opportunities existed. The evidence available did not show that there was universal dissatisfaction on this question in the Colonial Medical Service, and it was felt that some of the complaints resulted from restrictions necessarily imposed by the war. It was apparent, however, that in a few areas opportunities were by no means all that could be desired.

The Council has pursued this question with the Colonial Office and has asked it to consider the possibility of providing better professional opportunities in the Service. It is now understood that as a result of the appointment, since the end of the war, of many new practitioners to the Service, a considerable number of those already in the Service have been able to take the leave due to them, and many have completed or are now pursuing postgraduate courses leading to higher qualifications. The Colonial Office is satisfied that as further appointments are made the opportunities for study leave will become more favourable even than before the war.

Malayan Medical Service

136 The Council has received disturbing reports of the difficulties experienced by medical officers of the Malayan Medical Service on account of the extremely high cost of living in that country at the present time. The attention of the Colonial Office has been drawn to the position and the Department has been asked to give urgent consideration to the problem.

APPENDIX II

RULES OF THE CENTRAL ETHICAL COMMITTEE RELATING TO COMPLAINTS REGARDING PROFESSIONAL CONDUCT

Rule 1

Where a complaint is brought to the notice of the Head Office of the Association regarding the professional conduct of a member of the profession, a direction shall be obtained by the Secretary of the Association from the Chairman of the Central Ethical Committee as to whether in his opinion there is a *prima facie* case for investigation by the Association.

Rule 2

Where the Chairman is satisfied that there is a case for investigation, the Secretary shall inquire (subject to Rule 4 hereof) of the Honorary Secretary of the Division* of which the practitioner whose conduct is the subject of complaint is a member, as to whether the Division is willing to deal with the complaint in accordance with the procedure specified in its Ethical Rules. Where the practitioner whose conduct is the subject of complaint is not a member of the Association, a similar inquiry shall be made (subject to the provisions of Rule 7 hereof) of the Honorary Secretary of the Division in which the practitioner resides.

Provided that, where the complainant and the respondent reside in different Divisions of a Branch composed of several Divisions the Chairman of the Central Ethical Committee shall have power to direct that inquiry be made of the Honorary Secretary of the Branch as to whether, subject to the provisions of Rule 7 hereof in the case of a non member, the Branch Council is willing to deal with the complaint in accordance with the procedure specified in the Ethical Rules of the Branch and any such reference of a complaint to a Branch Council shall be deemed for the purpose of Ethical Rule 7 (d) of the Branch to be a reference from the Central Ethical Committee. Provided further that where the complainant and respondent reside in different Branches the complaint shall be dealt with by the Central Ethical Committee and no such inquiry shall be necessary.

Rule 3

Subject as hereinafter provided, the Central Ethical Committee may undertake the investigation of any complaint which is the subject of an inquiry of the Honorary Secretary of a Division or Branch under Rule 2 hereof unless the Division (or Branch) concerned, within twenty one days after the Central Ethical Committee has communicated with the Honorary Secretary of the Division (or Branch) in accordance with Rule 2 hereof shall have informed the Central Ethical Committee that it will deal with the complaint in accordance with its Ethical Rules.

Provided that, save in exceptional circumstances no investigation shall be undertaken by the Central Ethical Committee contrary to the wishes of the Division (or Branch).

Rule 4

Notwithstanding anything contained in Rules 2 and 3 hereof inquiry into the professional conduct of any member of the Association who is known to have accepted an appointment which was the subject of an 'Important Notice' in the *British Medical Journal* at the time of its acceptance shall be undertaken only by the Central Ethical Committee and acceptance of such an appointment by a member of the Association and/or refusal to resign from the same on a request being made in accordance with Rule 9 hereof, shall be construed as *prima facie* evidence of an ethical offence justifying expulsion from membership of the Association. In making inquiry into any such case the Central Ethical Committee may act on its own motion and without any formal complaint being received by the Association.

Rule 5

Complaints regarding the professional conduct of individual members of the profession shall be considered by the Central

* Including a Branch composed of one Division

Ethical Committee otherwise than in accordance with the provisions of Rules 3 and 4 hereof in the following circumstances only

(a) Upon a reference from a Division or a Branch Council or from the Ethical Committee of a Division or Branch

(b) Upon an appeal by a member of the profession to the Council of the Association from a decision of a Branch Council

(c) Upon a report being made to the Council of the Association by a Division or a Branch Council in order that the propriety of a member of the Association remaining a member may be considered

(d) Where the Division (or Branch) to which a complaint would ordinarily be referred under Rule 2 hereof has not adopted the Revised Rules governing procedure in ethical matters as approved by the Representative Body of the Association—provided that save in exceptional circumstances no investigation shall be undertaken in such a case by the Central Ethical Committee contrary to the wishes of the Division (or Branch)

(e) Where the parties concerned reside in different Branches of the Association

Rule 6

An appeal to the Council of the Association from a decision of a Branch Council under Rule 24 of the Branch shall be allowed only on one or both of the following grounds

(a) that an ethical principle has been wrongly interpreted or applied,

(b) that the decision given is against the weight of the evidence

In the event of such appeal to the Council of the Association the matter shall be dealt with by the Central Ethical Committee as a hearing *de novo* but no party shall be entitled to adduce evidence additional to that called before the Committee or Committees by whom the case has previously been investigated without the permission of the Chairman of the Central Ethical Committee. Any application for permission to adduce additional evidence shall be made to the Chairman not less than seven days before the date fixed for the hearing of the appeal

Rule 7

Save in exceptional circumstances no investigation shall be undertaken of a complaint by a non member of the Association or regarding the professional conduct of a non member of the Association unless the written consent of the non member and his agreement to be bound by the Ethical Rules of the Association a copy of which shall be sent to him, and to accept the decision of the Association as final and conclusively binding on him in all respects are first obtained

Rule 8

In a case submitted by a member of the profession who declares that he has been (or is) directly affected by what he alleges to be the unprofessional conduct of another practitioner it shall be the duty of the Secretary of the Association before appointing the direction of the Chairman of the Central Ethical Committee referred to in Rule 1 hereof unless the provisions of Rule 8 of the local Division (or Rule 9 of the Branch) have already been carried out to ascertain whether the complainant has either personally or by letter afforded the practitioner against whom he makes complaint a reasonable opportunity of explanation and if this has not been done to call upon him to do so. If the complainant fails to take this step within a reasonable period of his own making having made the complaint he shall be deemed to have withdrawn the complaint

Rule 9

In a case where a member of the Association is known to have accepted an appointment which was the subject of an ethical complaint in the *British Medical Journal* at the time of his appointment it shall be the duty of the Secretary of the

Association to request such member to take the necessary steps within a period of one calendar month to terminate such appointment in accordance with the terms of his engagement and no further action shall be taken under these Rules with respect to such member until the expiration of such calendar month

If the member shall within such period satisfy the Secretary of the Association that he has given such notice as is required under the terms of his engagement to terminate such appointment, no further action shall be taken under these Rules with respect to such member until the expiration of such notice

Rule 10

In a case of inquiry held for the purpose of considering the propriety of a member of the Association remaining a member the Secretary of the Association shall inform the member that the inquiry will be held in accordance with the Articles of Association* relating to expulsion and shall furnish him with a copy of the relevant sections of the Articles

In no case shall the Central Ethical Committee recommend to the Council of the Association that a member be expelled from membership of the Association except after an inquiry of which the member shall have received notice is provided in this Rule

Rule 11

An inquiry regarding the professional conduct of a member of the profession may be held either at an ordinary meeting of the Central Ethical Committee or at a special meeting, at the discretion of the Chairman of the Committee. Not less than twenty one days' notice of the meeting shall be given to every member of the Committee and to all parties concerned

Rule 12

(a) In all cases other than cases of appeal to the Council of the Association from a decision of a Branch Council, the Secretary of the Association shall inform the practitioner whose conduct is under consideration that a complaint regarding his conduct has been brought to the notice of the Central Ethical Committee and shall invite him to submit his written observations on the matter or to supplement any explanations he has given on any previous occasion

(b) The Secretary shall invite the complainant and the respondent to attend with their witnesses (if any) at the meeting of the Central Ethical Committee at which the case is to be investigated, and it shall be the duty of the Committee wherever practicable to arrange for the attendance of both parties at such meeting

(c) Each party shall send to the Secretary not less than fourteen days prior to the date of the meeting of the Committee at which the complaint is to be investigated copies of all documents on which he intends to rely

(d) Copies of, or relevant extracts from, all such documents furnished to the Secretary by either party shall be supplied by the Secretary to the other party

(e) The Committee shall investigate the facts of the case and shall take such evidence as shall be deemed by the Committee necessary for the purpose. Such evidence may, at the discretion of the Committee, be written or oral

Rule 13

The Committee shall after due investigation, adopt a Resolution in one of the following forms or in such other form as it may consider appropriate

(i) That, in the opinion of the Committee, the complaint has not been established

(ii) That in the opinion of the Committee there has been no violation of the Rules (or Resolutions) of the Association (or of the Division or Branch) or of the generally accepted principles of professional conduct and that no action be taken

* Relevant extracts of the Articles of Association would be inserted here as a footnote

(iii) That, in the opinion of the Committee, the complaint is frivolous, and that the case be dismissed

(iv) That, in the opinion of the Committee, has committed an indiscretion and error of judgment, but that his conduct does not call for censure

(v) That, in the opinion of the Committee, has violated

* (a) the Rules (or Resolutions) of the Association (or of the Division or Branch) and

* (b) the generally accepted principles of professional conduct,

but that, in consideration of faults on the part of others concerned, the case be dismissed

(vi) That, in the opinion of the Committee, has violated

* (a) the Rules (or Resolutions) of the Association (or of the Division or Branch), and

* (b) the generally accepted principles of professional conduct

and that he be, and hereby is, censured

(vii) That in the opinion of the Committee the conduct of has been (or is)

* (a) in violation of the Rules (or Resolutions) of the Association (or of the Division or Branch) and

* (b) detrimental to the honour and interests of the Association and

* (c) detrimental to the honour and interests of the medical profession,

and (in the case of a member) (1) that he be informed of this finding of the Committee and allowed until to reconsider his position, (2) that the Secretary of the Association be instructed to report in due course to the Committee upon his reply, if any, and (3) that, if upon such further report the Committee shall consider his reply unsatisfactory, or if no reply be received within the time specified, the matter shall forthwith be reported to the Council of the Association in order that the propriety of his remaining a member may be considered

(viii) That, in the opinion of the Committee, the conduct of has been (or is)

* (a) in violation of the Rules (or Resolutions) of the Association (or of the Division or Branch), and

* (b) detrimental to the honour and interests of the Association, and

* (c) detrimental to the honour and interests of the medical profession

and (in the case of a member) that the matter be reported forthwith to the Council of the Association, in order that the propriety of his remaining a member may be considered

The following resolutions are to be adopted only after inquiries held in accordance with the Articles of Association relating to expulsion

(ix) That it be recommended to the Council of the Association that the Council do not in the exercise of its powers under the Articles of Association, expel from membership of the British Medical Association of a member of the Division of the Branch

(x) That it be recommended to the Council of the Association that the Council in the exercise of its powers under the Articles of Association do expel from membership of the British Medical Association of a member of the Division of the Branch, on the ground that his conduct is deemed by the Council to have been (or to be)

* (a) detrimental to the honour and interests of the Association, and

* (b) detrimental to the honour and interests of the medical profession and

* (c) calculated to bring the profession into disrepute, and

* (d) such that he has wilfully and persistently refused to comply with the Regulations of the Association (or the Rules of the Division or Branch)

Rule 14

A copy of the Resolution of the Committee shall be sent by the Secretary of the Association to each of the parties concerned, and to the Honorary Secretary of any Division or Branch immediately concerned

Rule 15

If a practitioner shall make amends or express regret to the satisfaction of the Central Ethical Committee, it shall be competent for the Committee, after due notice, to rescind the Resolution of censure passed under Rule 13 (vi), and any such decision of the Committee shall be reported forthwith to any other authority of the Association which has already considered the case and shall be circulated in the same manner as the original Resolution of censure

Rule 16

The Resolution of the Committee upon a case, other than a case of inquiry in accordance with the Articles of Association relating to expulsion, shall be final unless new facts shall subsequently be brought forward which, in the opinion of the Committee, justify the case being reopened. Should such new facts be brought forward in a case which came before the Committee after a local investigation, the case shall be referred for reinvestigation by the Division or Branch concerned

Rule 17

After a case has been referred to the Central Ethical Committee for investigation, no person concerned shall make complaint to any other professional authority until such case has been disposed of by the Committee or, in a case of inquiry in accordance with the Articles of Association relating to expulsion, by the Council of the Association and if any such person shall do so the Committee or the Council (as the case may be) may at its discretion adjourn or refuse to proceed with the investigation

Rule 18

Any member of the Ethical Committee of a Division or Branch or of the Council of a Branch who shall have taken part in the previous consideration of any case referred to the Central Ethical Committee shall be debarred from taking part in the consideration of such case as a member of the Central Ethical Committee or the Council of the Association but he shall not be debarred from giving evidence as to facts if called upon to do so

Rule 19

(a) In every case in which the Central Ethical Committee shall after due inquiry in accordance with these Rules, have passed a Resolution declaring that in the opinion of the Committee the conduct of any medical practitioner, whether by contravention of the Rules and Resolutions of a Division or Branch or otherwise, has been (or is) detrimental to the honour and interests of the medical profession, it shall be the duty of the Secretary of the Association, subject to the approval of the Committee, to cause such Resolution to be brought directly to the knowledge of every member of the Division (or Branch) in the area of which such practitioner resides, and every member of such other Divisions or Branches as the Committee may specify, by means of a Notice in the form appended hereto which Notice it shall be the duty of the Secretary of the Association to authenticate by his signature

(b) In any case in which the Central Ethical Committee shall at the time of or subsequently to, the adoption of a Resolution of the nature contemplated by paragraph (a) of this Rule, have also resolved that, in the opinion of the Committee, it is desirable that such Resolution shall be brought officially to the notice of any specified Divisions or Branches of the Association

* Strike out (a), (b) or (c) if not required

* Strike out (a), (b), (c) or (d) if not required

shall be the duty of the Secretary of the Association to transmit copies of the said Resolution to the Honorary Secretaries of the Divisions or Branches so specified

Form of Notice referred to in Paragraph (a)

BRITISH MEDICAL ASSOCIATION

(Private and Confidential)

NOTICE

In pursuance of Rule 19 of the Rules of the Central Ethical Committee of the Association relating to Complaints regarding Professional Conduct, Notice is hereby given that at a meeting of the Committee held at on the day of a Resolution in the following terms was duly passed

That in the opinion of the Committee the conduct of of has been (or is) detrimental to the honour and interests of the medical profession

Signed in pursuance of the Rules of the Central Ethical Committee of the British Medical Association relating to Complaints regarding Professional Conduct

PROCEEDINGS OF COUNCIL

Adjourned Meeting, Wednesday April 16 1947

A meeting of the Council of the Association to complete the business adjourned from the meeting of April 2 (*Supplement* April 12 p. 53) was held on April 16. Dr H. Guy Dain presiding.

A report from the Consultants and Specialists Committee was presented by Mr A. M. A. Moore and contained recommendations, which were agreed to, for certain slight alterations in the rules relating to the roll of consultants and to the method of election of group committees. A recommendation transmitted from the Orthopaedic Group Committee was that the group should be composed of members of the Association practising exclusively or predominantly in orthopaedic surgery and who had been so practising for a period of not less than five years. It was pointed out that no other Association group had laid down a minimum limiting period, but as each group enjoyed autonomy and this was the wish of the Orthopaedic Group Committee, the Council acceded to the recommendation.

The principal subject in a report presented from the Services Committee was conscription, in particular a proposal that specialists might be permitted to defer their period of national service up to the age of thirty. This plan was not favoured by the committee, and it was pointed out that under such an arrangement there would be no necessary correlation between the number of specialists coming into the Services and the number actually needed. The feeling was that it was for the Services themselves, by their terms and conditions of service, to attract as permanent officers the specialists required. The Secretary said that in the Bill itself no option was provided whereby a man could take his period of service either before or after qualification although such option was referred to in a letter from the Ministry.

In presenting the report of the Charities Committee, Dr Janet Aitken proposed that from the unearmarked subscriptions to charities there be paid a sum of £250, being one third of the amount required to meet the return fare of fifty children of British doctors killed in the war who are to be the guests for three months of the Swiss medical profession. The proposal was agreed to.

Dr J. Thwaites reported for the Committee on Psychiatry and the Law. This is a joint committee of the British Medical Association and the Magistrates' Association. The report embodied a memorandum on the interpretation of the definitions in the Mental Deficiency Act, 1927, with an appendix on the psychopathic personality. The memorandum was approved by the Council for publication in the *Journal*. Dr Thwaites also stated that at the request of the Council the committee had considered the desirability of an alteration of the law relating to attempted suicide. It appeared to the medical members of the committee that there was a strong case for such alteration, so that attempted suicide—excluding 'suicide pacts' or the incitement of another person to commit suicide—would not be dealt with as a legal offence, but there were certain other legal issues which might arise, such as the question of life assurance, with which the members did not feel competent to deal. This report also was approved. The committee was complimented on it, and it was agreed that it be published in the *Journal*.

In the absence of the chairman of the Public Health Committee Dr J. A. Ireland brought forward a report recommending approval of a revised scale of fees for practitioners called in by midwives, such scale to be sent to the Ministry of Health with a request that the regulations be amended accordingly. This recommendation was approved, as was also a recommendation for a revised scale of remuneration for practitioners undertaking the examination of and attendance on children committed to the care of local authorities and boarded out.

Fees for Treatment of School Children

A report from the special committee on fees for the treatment of school children was brought forward by Mr Lawrence Abel. The committee had been asked to formulate proposals

for the revision of the scale of fees in the Ministry of Education circular 102. A deputation had attended at the Ministry of Education in support of the Association proposals. The Ministry had put forward counter-proposals, but these in certain respects appeared to be far from satisfactory.

The Council resolved to express its dissatisfaction at the Ministry's proposals (not yet confirmed) and to restate its case.

Mr H S Souttar, for the Science Committee brought forward recommendations which were agreed to for the award of two Sir Charles Hastings Clinical Prizes and for other prizes of the Association. Mr Souttar also reported on efforts made to interest medical students in the work of the Association. It was agreed to award six prizes, each of the value of £25, for essays by students in open competition in the country in general and in addition to award a number of regional prizes, the Students Association to decide on the selection of regions. A series of BMA lectures to medical students were also agreed to.

The Science Committee further reported on arrangements for postgraduate education, which it recommended should be arranged at regional level, with a committee established in each region for the purpose of co-ordinating and promoting postgraduate study, the committee to consist of representatives from the university the staffs of local hospitals, local medical societies, and the Divisions and Branches of the Association. A recommendation which set out these and other details was agreed to, and the Council in adopting the report endorsed a remark by the committee placing on record its appreciation of the very valuable contribution made by local medical societies and the clinical activities of Divisions and Branches over a number of years.

Colonial Advisory Committee

Dr J B W Rowe presented a report from the Dominions Committee, the principal matter in which concerned a suggestion first made a year ago that the Secretary of State for the Colonies should be asked to consider the appointment of a representative of the Association on the Colonial Advisory Medical Committee which advised the Secretary of State in the formulation of policy. The Secretary of State had replied that appointments to the committee were personal and not representative, but after further approach he had agreed that if the Association cared to submit a list of persons who, in its view, were fitted by their experience to be of service he would be very glad to consider their names when making appointments to the committee. The Council agreed to recommend the names of suitable practitioners.

A preliminary report from the Committee on the Care and Treatment of the Elderly and Infirm was presented. It was stated that, among other matters the committee was considering the special provision for the care and treatment of cases of senile dementia.

A resolution from the West Middlesex Division was received and noted that the executive committee viewed "with grave disquiet" the pressure brought to bear on representatives at the Special Representative Meeting by members of Council to persuade them to vote contrary to the instructions given them by their constituents.

In view of the possibility of active steps being taken shortly to bring about health centre development experimentally or otherwise, the Council considered as a matter of some urgency a proposal that an investigation be made forthwith into group practice and similar arrangements and various types of general practitioner collaboration. It was agreed to set up an *ad hoc* committee of nine members on this subject. The selection of the members of the committee was left in the hands of the Chairman of Council and the chairmen of certain standing committees.

The final task of the Council in a meeting which lasted rather more than two hours was to approve the Annual Report which is published in the *Supplement* at p 61.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Mr Ian Jackson, FRCS at 104 Harley Street, W1 (Welbeck 1801), Dr W Eric Gibb MRCP at 47, Queen Anne Street Cavendish Square W.1 (Welbeck 1011).

GENERAL MEDICAL COUNCIL

ELECTION OF DIRECT REPRESENTATIVE

In addition to Dr J A Brown, whose manifesto was published in the *Supplement* of April 19 (p 57), the following are standing as candidates for the vacancy on the G M C

JAMES EDGAR OUTHWAITE, M B, Ch B (Leeds)
ISAAC ROSE M B, Ch B (Leeds)

NEWLY QUALIFIED ASSISTANTS

POSITION IN RELATION TO MILITARY SERVICE

The Central Medical War Committee thinks it desirable to draw the attention of general medical practitioners to the fact that newly qualified practitioners liable to military service, although now free to accept assistantships in general practice are not free to remain in such appointments after they have been qualified for six months. The committee urges all newly qualified practitioners, in their own interests and the interests of the hospitals, to seek junior hospital appointments of the A category. A practitioner liable to military service is granted deferment to enable him to hold such a post for six months *provided that he has obtained the post within three months of qualification*. He is then granted a further six months deferment if selected for a B2 post, and if, on completing this post, he is appointed to a B1 post, his recruitment is again deferred, normally for twelve months at least, and he may eventually be recommended for recruitment as a graded specialist. If, however, he enters general practice on qualification, his recruitment is initiated about five months after the date of qualification with a view to call-up when he has been qualified for six months, and the committee will not then entertain an application for deferment for the purpose of gaining hospital experience before undertaking military service.

At the present time male practitioners are liable to military service as general duty medical officers if they were born on or after July 1, 1916.

HEARD AT HEADQUARTERS

Transatlantic Centenary

The American Medical Association celebrates its centenary this year. It is junior to the BMA by fifteen years. Societies unlike individuals, do not grow old, and both on this side of the Atlantic and on the other the bodies which represent the medical profession are youthful and aspiring. The Council is sending a delegation to convey greetings to our American colleagues in their week's celebration at Atlantic City, New Jersey in the middle of June, thereby returning the compliment which the AMA paid its elder brother in 1932.

National Health Bill American Version

The delegates to the American Medical Association centenary will find a National Health Service Bill under consideration in the United States—a Bill almost as lengthy and complicated though not as revolutionary, as the one which has lately passed through the British Parliament. A Bill has just been introduced into the Senate to co-ordinate the health functions of the Federal Government in a single agency. Its other purposes are to extend the activities of the public health service and to promote and encourage medical and dental research. In the preamble it is explained that health and medical functions are widely scattered at present with resulting confusion and duplication of effort, and that there are inadequacies in the distribution of public health services. The policy is to aid the individual States, which have a good deal of autonomy in the matter through consultative services and grants in aid 'to make available medical hospital, dental, and public health services to every individual, regardless of race or economic status. The Bill is to be an administrator appointed by the President on the advice of the Senate. He will be a medical man, licensed to practise in one or more States, and is expected to be outstanding.

in the field of medicine. His salary, or compensation as the Americans call it is to be at the rate of \$15,000 a year

The Aged and Infirm

The problem of the care and treatment of the elderly and infirm which is at present engaging the attention of a special BMA committee presided over by Dr A Greig Anderson is proving a bigger problem than it seemed to be at the outset. The committee has begun by classifying the elderly and/or infirm (it seems impossible to escape the ugly double conjunction) and has found that there are at least five classes to be considered—namely, the elderly the elderly and infirm the long term and short term sick and the senile psychiatric case. As to speak of other special groups in equally cumbersome phrases. The long term and short term sick have again to be subdivided into acute sick, prolonged acute sick, long term sick potentially remediable and long term sick irremediable. Senile psychiatric cases again have to be divided into those not requiring admission into a mental institution and those suitable for such admission. The committee is pursuing its task so thoroughly that an important contribution to social medicine is likely to emerge from its discussions. One matter to which it is devoting itself especially is the ascertainment of the provision and the need of homes and hostels for the elderly and it has had before it particulars of some interesting enterprises of this kind.

Correspondence

Municipal Medical Officers

SIR—Doubtless you are aware that from April 1948 the majority of the municipal health services are being transferred to the Regional Boards of the National Health Service. Doctors in the municipal services, whatever their political leanings, view with mixed feelings the trends of the negotiations at present being conducted with the Minister. They can think of many aspects of municipal medical practice which they dislike and do not wish to see perpetuated. For example experience in the public service has convinced them that unless the profession is powerfully and completely represented at all levels good will and hard work are ineffective against the tremendous inertia of a preoccupied Authority. If asked they would certainly say "No concessions without representation." On the other hand they have no desire to be taken over by colleagues who, however enthusiastic and professionally well equipped, look upon municipal practice as a means to an end rather than a service to the public in which there are no disjunctions drawn between "lectures" and "interesting cases."

Quite apart from these future political conditions in the municipal services are far from ideal. Medical officers feel that they have lost out much more for dealing directly with their consulting bodies on day-to-day matters and questions of policy. They have no voice in their terms of service or remuneration and with few exceptions their approval of the conditions suggested for transfer has been their willingness to bear the burden of the change.

A National Association of Municipal Medical Officers is being formed to bring before the attention of the Ministry of Health the views of medical officers of non-NHS services. Will you do me the honor to please communicate this to the Hon. Secretary, S. Castle Bar Road, Ealing, London W.5. I shall be pleased to send further particulars and would be glad to hear of any further developments.

J J HAMILTON

"Doctor" Sign on Cars

SIR—The fact that a doctor's car is the only one in the street which is not liable to be stopped by the Police for a "doctor's sign" is a very curious one. It is a pity that the Police do not seem to be aware of this. The Police should be made aware of this and the fact that a doctor's car is the only one in the street which is not liable to be stopped by the Police for a "doctor's sign".

great white shining specialist attitude is one of the things which has allowed the public to think of us as it does—I am, etc

London W 1

C K VARTAN

SIR—Your correspondent Lieut-Col F A Barker (*Supplement* March 22 p 41) who referred to the usefulness of these labels in getting us sympathetic treatment by the police has brought up one of their most useful functions. Many of my patients live in blocks of flats in the area of London within which parking is strictly controlled. Before I had a Doctor label on my car I was constantly having trouble with the police, but since my car has been labelled I have met with every possible kind assistance. I see every reason therefore to continue using the label since so far as parking is concerned a state of emergency still exists—I am, etc

London SW

J H B BRAT

National Service

SIR—The conscription age for doctors under the National Service Bill will be about 25 years, with a deferment to 29 for intending specialists. Other professions will have to do their term of conscription at the age of 17½. I suggest that doctors should also do half their service at that age so that they will have served in the ranks and will be able to understand Service life from that aspect. If deferment is granted until after qualification doctors will be the only persons almost who will not have served in the ranks if called up later in an emergency.

If half of their service was done at the age of 17½ their medical education could start at 18, and the student would have a wider outlook on life. Eighteen anyway, is considered to be the most advantageous age for starting. During this six or nine months the intending student would learn discipline, drill etc., and also, if in a medical branch, some nursing-orderly duties. Even this slight experience of nursing would give a doctor some idea of the work that has to be done in a ward. The second half of the conscription period would be done after qualification and would include the learning of officers' administrative duties and instruction in anti-gas and anti-bacterial warfare, tropical medicine, and hygiene. All of these are very scantily taught in the present medical curriculum. All doctors in my opinion, should do their second half of service soon after qualification, and there should be no further deferment for specialists. I would have thought that the drafting of conscripted specialists into any hospitals in peacetime would have spoiled the field for intending specialists in the regular R A M C.

I think any medical officer who was drafted into the Army and went straight from his training depot to a regimental or field ambulance unit will agree that he required more instruction in Army routine and administration than he got at his training depot. He usually found that he had to learn it from his medical orderlies or brother officers. By this splitting of the conscription periods for doctors I consider that all doctors will be more valuable to the service if called up in an emergency in that they will be conversant with all sides of Service life and will not have used their conscription time in only extending their clinical knowledge—I am, etc

Colonel Medical Service
The Guards

W E HADDEN

The Superannuated and the NHS

SIR—One must admire and applaud the spirit of service shown by the various negotiating bodies of the BMA in undertaking thankless tasks and giving much precious time on behalf of their professional brethren. All praise to them therefore for their unselfish and heroic labours. That acknowledgment having been made I should like to support emphatically Dr C H Barber's plea (*Supplement* April 5 p 50) for adequate pensions for the superannuates-designate who are about to be "axed" out of further medical service to the community. No doubt the subcommittee concerned is pursuing this matter with all diligence and so I would urge them to continue to force it on the Ministry's attention in season and out of season until such elementary justice is secured—I am, etc.,

Branch and Division Meetings to be Held

NORTH WALES BRANCH—At Royal Oak Hotel, Bettwsycoed, Wednesday May 7, 2.30 p.m. Dr Robert Coope (Liverpool) Suppurative Pneumonias and Lung Abscess.

MID ESSEX DIVISION—At St John's Hospital, Wood Street Chelmsford, Sunday, May 4, 10.30 a.m. Mr Alan Brews Obstetrics in General Practice

Meetings of Branches and Divisions

WESTMINSTER AND HOLBORN DIVISION

A general meeting took place on March 27 to discuss the present hospital position in London. Dr W. A. Milligan was in the chair. Those present included the medical officers of health for Westminster and Holborn, the Hon. Arthur Howard, M.P., Dr Harkness, medical officer for London County Council, and Mr C. M. Power, house governor of Westminster Hospital.

Dr Harbour said it was obvious that the hospital bed position had broken down, especially for the chronic sick. He acknowledged the help of the district nurses and home helps, but found both too limited in number. Westminster with at least ten thousand old people living alone could rely only on St Mary Abbots Hospital which now had 240 beds for the chronic sick. The reasons for the lack of L.C.C. beds were lack of nurses and domestic staff and lack of repair to war damage. He urged persuasion of nurses to the L.C.C. hospitals and away from the voluntary hospitals which appeared to him to be overstaffed. As regards domestic staff, foreign labour must be imported, some domestic work might be done by relatives of those in hospital. Regarding building difficulties he deplored that the Ministry of Health did not give every facility for such work. He suggested the revival of emergency hospitals and rest centres. As regards voluntary hospitals the rebuilding problem was not so large, but the domestic difficulty remained. He regretted that the voluntary hospitals would not admit their proper proportion of the chronic sick. Another point he made was the encroachment of all private beds on public ones, the former being wasteful to all non-medical personnel.

Mr J. S. Batchelor said that there must be a selection of cases for the teaching hospitals. The chronic sick were catered for as outpatients, so that a greater number of nurses were needed for the teaching hospitals to run the clinics.

Dr Shinnie said the problem was not purely medical. Thirty years ago the population of Westminster was much larger and there had been no difficulties in getting beds at St Stephen's. Nowadays more people desired to be in hospitals and old people had no one to look after them—the result of two generations of small families. The preventive services for old persons, such as Westminster Council were providing, was a partial solution.

Dr Harkness said he had not heard anything he did not already know, but the L.C.C. knew the position. There had been only one previous nursing breakdown, during an influenza epidemic. Some beds were lost from war damage but there was plenty of accommodation and there were not the nurses to serve them. Hospital repairs had priority and the lack of rebuilding was not urgent. He agreed that nurses went to voluntary rather than to L.C.C. hospitals, the fundamental difference being the type of work—that met with in L.C.C. hospitals being unpopular. As regards the part time campaign, 600 or so nurses had applied. This would not allow more beds to be opened but it would relieve the strain on the present nurses.

Mr C. M. Power spoke for the voluntary hospitals and deplored the conditions especially for the chronic sick. His hospital—Westminster—had no nursing shortage, no domestic shortage, nor rebuilding difficulties. Private wards did not detract from hospital accommodation and he refuted that the staff had priority of beds for fees. The L.C.C. had 10,000 out of 23,000 beds shut down. He thought that their shortage of nurses was due to the fact that nurses are not willing to spend long periods nursing the same type of cases such as cancer or tuberculosis and that the nurses' living conditions were bad.

Mr Arthur Howard, M.P., said that he was encouraged by the fact that all present had put the patients' troubles first but repeated that party politics should not be brought up in this connexion. He thought the L.C.C. were over-centralized and over-rigid in their organization.

It was decided not to pass any resolution on the matter but Mr Howard volunteered to get in touch with the Minister of Health with a report on the meeting.

POSTGRADUATE NEWS

The Edinburgh Postgraduate Board for Medicine announces that in connexion with the postgraduate courses in medicine and surgery a series of open lectures on subjects of wide biological interest will be given during the Summer term in the West Medical Lecture Theatre of the Royal Infirmary on Tuesdays April 29, May 13 and 27, and June 10 and 24, at 5 p.m. All graduates and students are invited to attend the lectures details of which will be published in the next column of the Supplement.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND Lincoln's Inn Fields, W.C.—Lectures in Anaesthesia. Fee for whole course £5 5s or £3 3s. Monday, April 28, 5 p.m. Dr Frank Evans. Spinal Analgesia. Tuesday, April 29, 5 p.m. Dr A. D. Marston. Anaesthesia in Obstetric Practice. Lectures in Otolaryngology. Fee for whole course £5 5s or £3 3s. Monday, April 28, 6.15 p.m. Prof. R. Willis. The Pathology of Tumours of the Nose and Throat. Tuesday, April 29, 6.15 p.m. Chemotherapy and Antibiosis in Otolaryngology, Wednesday, April 30, 6.15 p.m. Mr C. Gill Carey. The Treatment of Chronic Maxillary and Ethmoidal Sinusitis. Friday, May 2, 6.15 p.m. Mr F. C. W. Capps. Malignant Disease of the Paranasal Sinuses.

ROYAL SOCIETY OF MEDICINE

Section of Odontology—Monday, April 28, 6 p.m. (Cases at 5.30 p.m.)

Section of Neurology—Thursday, May 1, 8 p.m. Annual General Meeting. Election of Officers and Council for 1947-8. Paper by Dr Erik Lindgren (Stockholm). The Normal Temporal Horn and its Deformities by Tumours in the Middle Cerebral Fossa.

Section of Otolaryngology—Friday, May 2, 10.30 a.m. Annual General Meeting. Election of Officers and Council for 1947-8. Paper by Mr E. C. Naylor Strong. The Design and Application of Electronic Hearing Aids.

Section of Laryngology—Friday, May 2, 2.30 p.m. Annual General Meeting. Election of Officers and Council for 1947-8.

Section of Epidemiology and State Medicine—Friday, May 2, 3 p.m. Meeting at Common Cold Research Unit, Harvard Hospital, Salisbury. Short Papers by Dr W. H. Bradley. The History of Harvard Hospital and of the Common Cold Research Unit. Dr C. H. Andrewes. The Plan of Research into the Aetiology of the Common Cold. Dr D. K. M. Chalmers. Routine of Experiments with Human Volunteers. Dr F. Fulton. Interim Report on the Results of Transmission Experiments. Volunteers' flats and the M.R.C. Air Hygiene Unit will be demonstrated.

Section of Anaesthetics—Friday, May 2, 5.30 p.m. Annual General Meeting. Election of Officers and Council for 1947-8. Short Papers by Dr E. Trier Moersch. Controlled Respiration by means of Special Automatic Apparatus as used in Denmark and Sweden. Dr J. Clutton Brock. Skin Temperature as a Clinical Aid During Anaesthesia. Dr R. P. Shackleton. Anaesthetics in Yugoslavia.

Section of Surgery—Friday, May 2, 2 p.m. Meeting at Royal Sheffield Infirmary and Hospital. Saturday, May 3. Meeting in Sheffield continued. Election of Officers and Council for 1947-8.

CAMBRIDGE UNIVERSITY REGENT HOUSE—Friday, May 2, 5 p.m. British Association's Radford Mather Lecture by Sir Howard Florey. Penicillin and other Antibiotics.

LONDON UNIVERSITY COLLEGE—Friday, May 2, 5.15 p.m. Dr J. F. Danielli. Surfaces and Drug Actions.

EDINBURGH UNIVERSITY—Monday, April 28, 5 p.m., Dr Douglas Guthrie. Medicine in Greece and Rome.

ROYAL PHOTOGRAPHIC SOCIETY MEDICAL GROUP, 16, Princes Gate, S.W.—Thursday, May 1, 6.30 p.m. Mr E. B. Brain. Some Aspects of Medical Photography.

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At West Medical Lecture Theatre, Edinburgh Royal Infirmary, Tuesday, April 29, 5 p.m. Dr J. Russell Greig. Studies in Comparative Medicine.

GLASGOW UNIVERSITY DEPARTMENT OF OPHTHALMOLOGY—Wednesday, April 30, 8 p.m. Dr A. Mellick. Heterophoria.

LONDON SCHOOL OF DERMATOLOGY 5 Lisle Street, Leicester Square, W.C.—Tuesday, April 29, 5 p.m. Dr R. M. B. MacKenna. Principles and Practice of Treatment. Thursday, May 1, 5 p.m. Dr H. Corsi. Diseases of the Nails.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BECKETT—On April 20, 1947, at St Mary's Hospital, London, to Lyn, wife of Dr H. Dale Beckett, a son.

CURRIE—On April 13, 1947, at the North Middlesex Hospital, to Ysobel (née Garland), wife of Donald Currie, M.B. Ch.B., a daughter—Margaret Anne.

DUNLOP—On April 9, 1947, at Queen Charlotte's, to Monica, wife of Dr Eric Dunlop, a daughter—Jane Elizabeth.

ILAND—On March 24, 1947, to June, wife of Dr C. N. Iland, Sedgfield, two daughters.

MARRIAGE

HOWAT-HARKER—On April 18, 1947, at Goath and Yorkshire, James M. L. Howat, M.B. Ch.B., to Margaret E. Harker, M.R.C.P.

DEATHS

COPEMAN—On April 11, 1947, at 8 King's Gardens, Hove, S. Monck, Copeman, M.D., F.R.S., F.R.C.P., T.D., Knight of Grace of Order of St. John of Jerusalem in his 86th year.

DEACON—On April 18, 1947, at Carlisle, Mary, Ariel Stewart Deacon, M.B. Ch.B., D.P.H., aged 75, of Rannardale, Cockermouth, and late of Esplanade, Waterloo, Liverpool.

EMIN—On April 8, 1947, at 16 Cheyne Walk, N.W. 4, Michael Emin, C.M., aged 79.

LONDON SATURDAY MAY 3 1947

FOLIC ACID AS A THERAPEUTIC AGENT

BY

L S P DAVIDSON, BA, MD, FRCPEd & Lond, FRSEd
Professor of Medicine University of Edinburgh

AND

R H GIRDWOOD, MB, FRCPEd, MRCP Lond
Lecturer in Medicine University of Edinburgh

has been amply demonstrated in animal experiments by numerous workers that a deficiency of folic acid, however induced, has a profound depressing effect on the production of red cells, white cells, and platelets. The clinical application of this work was immediately recognized by physicians, but therapeutic trials were unsatisfactory until preparations of folic acid derived from natural products of vegetable and animal origin were replaced by *Lactobacillus* factor synthesized by Angier *et al* (1945). Reports of the therapeutic value of this substance in certain types of anaemia and intestinal syndromes have been published in America (Berry and Spies, 1946, Zuelzer and Ogden, 1946, Lopez, Spies, *et al*, 1946, Doan, 1946) and in Great Britain (Wilkinson, Israels, and Fletcher, 1946, Davidson and Girdwood, 1946). By courtesy of Messrs Lederle, Inc., we have been supplied with sufficient synthetic folic acid to treat 48 patients suffering from a variety of disorders of the blood and alimentary tract. This paper comprises a report on the therapeutic results obtained, a discussion of the mechanism underlying the action of folic acid, and a comparison of our findings with those recorded by other workers. The haematocritometer used in this investigation was of the type used by Angier *et al* (1945) and gave a reading of 13.8 g per 100 ml.

Pernicious Anaemia

Seventeen cases have been treated with folic acid given in various doses and by different routes of administration. The results are shown in Table I. An effective

Anaemia treated with Folic Acid

Case	Sex	Age	Hb	RBC (Mill's)	Reticulocyte	Folic Acid	
						Peak	Days
1	M	21	52	1.25	40.0	9	20 mg orally
		20	50	3.51			
		70	100	3.78			
2	M	1	36	2.05	10.0	10	10 mg
		81	104	2.92	9.0	5	5 mg
				2.85			
3	M	1	6	1.20	2.9	8	2.5 mg
		29	90	2.05			
4	M	1	46	1.55	2.0	8	1 mg
		14	72	1.56			
5	F	1	70	1.0	25.2	13	1 mg
		37	15	3.57			
6	F	1	6	1.50	7.2	27	5 mg
		25	72	1.5		20	mg

haemopoietic response was obtained from the daily oral administration of folic acid in doses of 2.5 mg in four cases, 5 mg in two cases, 10 mg in three cases, and 20 mg in one case. It is clear that folic acid alone in a dosage of 5 mg daily can restore the blood level quantitatively and qualitatively to normal (see Case 3). Folic acid in a daily dose of 1 mg by mouth was given to two patients. In one no change in the blood level occurred, whereas in the other there was an excellent haemopoietic response as shown in Table I (Case 6). In a third case no response was obtained from the daily intravenous administration of 1 mg for 14 days. A marked fall in the blood level occurred, necessitating a blood transfusion. A subsequent response to 5 mg of folic acid intravenously resulted.

200 mg of folic acid intramuscularly and 400 mg orally in a single dose given to two cases of pernicious anaemia produced no unpleasant side-effects, and there were excellent initial haemopoietic responses, which however, lasted only for 14 days. Large single doses appear to be a wasteful method of administration, since the same quantity of folic acid given in 5- or 10-mg doses daily produces a much greater total rise in the red cell count.

Sensitivity to Liver Extract—Case 1 was sensitive to parenteral liver therapy, as indicated by severe local and general reactions. But no such reactions occurred when synthetic folic acid was given orally, intracutaneously, or intramuscularly to this case and to three others of our cases of pernicious anaemia sensitive to parenteral liver therapy.

Failure to Respond to Folic Acid—Case 7 was the only one which failed to respond to folic acid, although it was typical of pernicious anaemia in every respect. The patient's erythrocytes reached a level of 5,660,000 per cmm on subsequent treatment with "anahaemin". Other points of particular interest in this case were:

1 That severe agranulocytosis developed during treatment with folic acid the white cell count falling to 800 per cmm and the temperature rising to 105° F (40.6° C) accompanied by marked prostration.

2 The febrile reaction responded to penicillin therapy and the white cell count started to rise after 48 hours' treatment with 150 mg of pyridoxine daily by mouth, reaching a peak of 9,000 per cmm after 8 days' treatment. Three days after cessation of treatment with pyridoxine the patient developed multiple peripheral neuritis which progressed to a complete paralysis of all four limbs with total loss of reflexes. Eventually she made an excellent recovery. The cause of the peripheral neuritis remains obscure. The

possibility that the metabolic effect of vitamin B₁ was antagonized by the preceding administration of folic acid and pyridoxine, both members of the vitamin B₂ group, was considered, but was rejected in favour of a diagnosis of infective polynucritis. No satisfactory explanation of the failure of Case 7 to respond to adequate amounts of folic acid is available unless it be postulated that the virus causing the infective polynucritis inhibited the expected therapeutic response and was also responsible for the development of the agranulocytosis.

Subacute Combined Degeneration of the Cord

Three patients suffering from subacute combined degeneration of the cord were treated with folic acid. In two of these cases no subjective or objective improvement resulted, while in the third case the neurological features deteriorated rapidly coincidentally with a marked improvement in the blood level. The features of this case were as follows.

The patient was a woman aged 30. Her haematological findings were Hb, 36% red cells 1,500,000 per cmm, CI 1.2. The bone marrow was megaloblastic, and gastric analysis showed a histamine fast achlorhydria. She gave a history of weakness of several years duration. For four weeks she had noticed that she was unsteady on her legs and she had suffered from paraesthesia of the arms. The neurological abnormalities on admission were as follows. Generalized muscular weakness in the legs without any wasting, loss of vibration sense below the level of both knees with loss of position sense, dorsiflexor plantar reflex on the left side with a doubtful reflex on the right side. Both ankle-jerks were absent, and the knee jerks were impaired. There was ataxia of both legs. During folic acid therapy the patient became completely incapacitated. Both plantar reflexes became dorsiflexor, the incoordination became extreme and the knee-jerks could not be elicited. Marked improvement in the symptoms and signs referable to the central nervous system resulted from intensive parenteral treatment with anahaemin. The significance of these observations is discussed later.

Refractory Megaloblastic Anaemia

We have previously reported the response of three cases of refractory megaloblastic anaemia to folic acid (Davidson and Girdwood, 1946). Further information is now available about the subsequent course of two of them. Case 8 in our previous report, which had been completely refractory to large doses of anahaemin, showed an initial response to folic acid therapy followed by a further improvement on proteolysed liver, the blood count reaching 50% Hb and 2,780,000 red cells per cmm. During the next six months he had three courses of folic acid at intervals, which resulted in a slow but steady rise in the red cell count to 4,990,000 per cmm.

In Case 9 in our previous report the Hb rose to 96% and the erythrocytes to 4,150,000 per cmm on folic acid. The macrocytic blood picture, however, persisted. His blood count was restored to complete normality with proteolysed liver ("hepamino"). Two further cases of refractory anaemia are now reported. The blood findings and treatment of one of these are shown in the accompanying graph. The patient was a woman aged 63. She had complained of progressive weakness over a period of two years. A year before admission she developed symptoms of angina pectoris on exertion. She had had loose motions for two years. The stools were watery but never large, bulky, or greasy in appearance. Sometimes her tongue was very sore. On examination she was pale with a yellowish tinge in the skin, the tongue was clean, shiny, and atrophic, no abnormality was found in the central nervous system, she was passing from 2 to 5 stools a day. A fat balance test which was carried out according to the method of

Cooke, Elkes, *et al* (1946) showed 31.4% total fat and 89.7% absorption. There was therefore no definite evidence of poor absorption of fat. Free hydrochloric acid was present in the test meal after histamine, and the marrow was megaloblastic.

A study of the graph shows that the patient was refractory to parenteral liver therapy, as there was no alteration in the blood level or in the megaloblastic character of the bone marrow despite the fact that after each injection liver extract an increase of reticulocytes occurred. For

Graph of a case of refractory megaloblastic anaemia treated with 20 mg of folic acid orally per day.

acid produced a third rise in reticulocytes and a gain of 2,330,000 red cells per cmm and 40% Hb in 51 days. Since the blood picture still remained slightly macrocytic (CI, 1.12) and the blood level subnormal after 51 days treatment with folic acid the haemopoietic response cannot be assessed as entirely satisfactory.

The second case was that of a woman aged 70 whose blood picture and clinical findings were typical Addisonian pernicious anaemia. She had received parenteral liver therapy for months, including six injections of anahaemin in the six weeks before admission, but the bone marrow was still megaloblastic. After admission she was given a single injection of 4 ml of anahaemin. This produced a reticulocyte crisis of 14.2% and a slight rise in the blood level, but the bone marrow remained megaloblastic. The haemoglobin was now 44% and the red cell count 1,930,000 per cmm. Folic acid in a dose of 25 mg daily by mouth produced a second reticulocyte crisis and a gain of 1,300,000 red cells and 34% haemoglobin in 30 days. The bone marrow was changed to a normoblastic state.

Aplastic and Hypoplastic Anaemia, Leucopenia, and Thrombocytopenia

The results of treatment in aplastic anaemia, leucopenia and thrombocytopenia are given in Tables II, III, and I respectively. It will be noted that no therapeutic benefit ensued either in the cases whose causation could not be determined (i.e., idiopathic) or in those arising secondary to some recognizable cause (i.e., symptomatic).

The Sprue Syndrome

Ten cases of the sprue syndrome have been treated with folic acid. They comprise four cases of tropical sprue, three cases of idiopathic steatorrhoea, and three cases of coeliac disease. The character of the anaemia present and the effect of treatment with folic acid, together with det-

of the case histories, clinical features, and fat-balance tests before and after treatment, have been recently recorded (Davidson, Girdwood, and Innes, 1947). Accordingly it is only necessary to give a short summary of the results obtained.

TABLE II—*Aplastic and Hypoplastic Anaemia treated with Folic Acid*

Case	Age	Sex	Diagnosis	Folic Acid (Oral)		Hb%		R B C (Mills)	
				Dosage	Days	Before	After	Before	After
16	75	F	Idiopathic hypoplastic anaemia	20 mg 10 mg	1-21 22-28	78	54	3 50	2 97
19	65	M	Idiopathic aplastic anaemia	20 mg	1-8	46	40	2 0	1 63
24	14	F	Idiopathic aplastic anaemia	20 mg (2 pints blood on 5th day)	1-17	40	38	1 96	2 02
18	68	M	Hypoplastic anaemia (after sulphonamides)	20 mg	1-15	50	56	2 07	2 06
17	42	M	Aplastic anaemia (following x ray therapy for reticulosis)	20 mg (1 pint blood on 3rd day)	1-14	64	44	3 11	3 24

TABLE III—*Leucopenia treated with Folic Acid*

Case	Age	Sex	Diagnosis	Folic Acid (Oral)		White Cell Count	
				Daily Dosage	Days	Before	After
7	49	F	Idiopathic agranulocytosis	5 mg	2-15	2 000	800
16	75	F	Idiopathic hypoplastic anaemia	20 mg	16-25	3 400	3 000
19	65	M	Idiopathic aplastic anaemia	20 mg	1-21	1 600	1 400
24	14	F	Idiopathic aplastic anaemia	10 mg	22-28	2 800	2 400
18	68	M	Hypoplastic anaemia (after sulphonamides)	20 mg	1-15	1 900	1 400
17	42	M	Aplastic anaemia following x ray therapy (Reticulosis)	20 mg	1-14	2 000	2 000
20	52	M	Leucopenia following x ray therapy (Reticulosis)	20 mg	1-11	2 800	2 200
21	25	F	Leucopenia following x ray therapy (Cerebral tumour)	20 mg	1-13	3 200	2 200
43	38	M	Leucopenia following x ray therapy (Spondylitis ankylopoietica)	20 mg	1-14	2 000	3 100

TABLE IV—*Thrombocytopenia treated with Folic Acid*

Case	Age	Sex	Diagnosis	Folic Acid (Oral)		Platelets per c mm	
				Dosage	Days	Before	After
22	25	F	Idiopathic thrombocytopenic purpura	20 mg	1-14	40 000	30 000
23	14	F	Idiopathic thrombocytopenic purpura	20 mg	1-10	20 000	10 000
19	65	M	Idiopathic aplastic anaemia	20 mg	1-8	60 000	35 000
24	14	F	Idiopathic aplastic anaemia	20 mg	1-17	20 000	10 000
18	68	M	Hypoplastic anaemia (after sulphonamides)	20 mg	1-15	115 000	95 000
17	42	M	Aplastic anaemia following x ray therapy (Reticulosis)	20 mg	1-14	75 000	25 000
20	52	M	Leucopenia following x ray therapy (Reticulosis)	20 mg	1-11	95 000	75 000
21	25	F	Leucopenia following x ray therapy (Cerebral tumour)	20 mg	1-13	190 000	105 000
43	38	M	Leucopenia following x ray therapy (Spondylitis ankylopoietica)	20 mg	1-14	85 000	83 000

1 Haematological Response—This was considered to be unsatisfactory in nine out of ten cases since treatment either produced no significant rise in the red cell count or failed to restore the blood level and haematological picture to normality.

2 Fat absorption as estimated by the fat-balance test of Cooke, Elkes *et al* (1946) was unaltered in five out of six cases.

Dramatic control of the diarrhoea and rapid clinical improvement occurred in the cases of tropical sprue and idiopathic steatorrhoea. In contrast no beneficial effects were noted in the cases of coeliac disease.

We should like to draw attention to one particular point which so far as we are aware has not been presented

before—namely, that a most remarkable alteration in intestinal function occurs on or about the fifth day of treatment with folic acid, at a time when no alteration of the blood level or even a rise in the reticulocyte count may have resulted. Moreover, this dramatic clinical change may occur in patients who subsequently show a complete or partial failure in their haematological response to continued folic acid therapy. This finding suggests that folic acid has at least two entirely separate actions—the control of the normal functioning of the haemopoietic and of the alimentary system. Since there may be a coincidental deficiency of other factors that are undoubtedly required for the normal functioning of these systems in addition to folic acid it is understandable why the correction of one deficiency may not result in the expected improvement. Only on such a basis is it possible to explain the findings discussed above and the failure of folic acid alone to restore the blood picture qualitatively and quantitatively to normal in certain patients suffering from the sprue syndrome and from idiopathic refractory megaloblastic anaemia.

Idiopathic Ulcerative Colitis

In view of the remarkable effects claimed by Carruthers (1946) in five cases of severe diarrhoea of unknown aetiology treated with folic acid for a few days we decided to assess its value in idiopathic ulcerative colitis. Five cases were accordingly selected for treatment because of their prolonged history and typical stool and sigmoidoscopic findings. After a carefully controlled observational period folic acid was given in doses up to 60 mg daily for periods varying from six to eleven days. Neither the clinical state of the patients nor the sigmoidoscopic appearances of their bowel were significantly altered. In fact, two of the cases were definitely worse at the end of treatment.

Discussion

The investigations reported above are in general agreement with those of other workers in this field—namely, that a haematological response to folic acid will be obtained only in patients suffering from a megaloblastic form of anaemia. When leucopenia and thrombocytopenia are part of a nutritional syndrome resulting from a deficiency of folic acid an increase of leucocytes and thrombocytes will result from folic acid therapy. When anaemia is of the normoblastic type, or when leucopenia or thrombocytopenia develops from causes other than a specific nutritional deficiency, folic acid will be found to be ineffective as a therapeutic agent.

Evidence recently accumulated by Welch *et al* (1946) and by Bethell *et al* (1947) helps to throw light on these clinical findings and affords a basis for explaining the mechanism by which folic acid functions. There now appears to be little doubt that free folic acid (pteroyl-glutamic acid) is the factor which is essential for the continuation of normoblastic blood formation, and a deficiency causes a reversion of the bone marrow to the megaloblastic state.

Free folic acid is liberated in the body from its conjugated form, which is present in various foodstuffs. A deficiency of free folic acid may arise in various ways—e.g., a failure in intake of conjugated folic acid (nutritional macrocytic anaemia), a failure in absorption of conjugated folic acid (sprue syndrome), or a failure in the liberation of free folic acid from its conjugate form (Addisonian pernicious anaemia). In this last disease it should be noted that the haemopoietic response to folic acid and purified liver extracts given parenterally is identical, although such extracts contain only minute traces of folic acid. This apparently anomalous finding can be explained on the

following basis. When free folic acid (pteroylglutamic acid) is given to patients with pernicious anaemia a haemopoietic response occurs accompanied by a transformation of the megaloblastic bone marrow and a marked increase of excretion of free folic acid in the urine. When conjugated folic acid (pteroylheptaglutamic acid), as contained in natural foods such as yeast is given in equivalent doses no transformation of the megaloblastic marrow occurs and no increased excretion of free folic acid results. When purified liver extract is given parenterally to a case of pernicious anaemia the classical haemopoietic response occurs together with a marked excretion of free folic acid. Hence it can be assumed that purified liver extracts contain a factor which enables the conversion of conjugated folic acid to free folic acid to take place. This liberating factor, which is the product derived from the interaction of Castle's intrinsic and extrinsic factors in the alimentary tract, is absorbed from the intestine and stored in the liver. It is present in the liver of normal individuals but not in the liver of patients with pernicious anaemia. This liberating factor is hereafter referred to as L.F. The cause of pernicious anaemia therefore does not lie in some inherent abnormality of the bone marrow but in the inability of the body to convert conjugated folic acid to the free form through lack of L.F. The administration of preformed free folic acid to a patient with pernicious anaemia circumvents the need for this conversion and accordingly the expected haemopoietic response occurs.

It is well recognized that patients suffering from nutritional macrocytic anaemia, the sprue syndrome, pernicious anaemia of pregnancy, and idiopathic refractory megaloblastic anaemia may be partially or completely refractory to the injection of potent purified liver extracts despite the presence of a megaloblastic marrow. Such patients will respond to the oral administration of whole liver (Fullerton, 1943), proteolysed liver (Davis and Davidson, 1944), or liver extract (Watson and Castle, 1946). The introduction of folic acid has added another therapeutic weapon effective in this group of diseases. Megaloblastic blood formation in the above conditions is not primarily conditioned, as in Addisonian pernicious anaemia, by a defective production of L.F. but by a deficiency in the body of conjugated folic acid as a result of direct dietary deficiency or a failure in absorption. Hence it is understandable why parenteral liver therapy fails and why free folic acid is effective under these circumstances.

The mechanism by which proteolysed liver and oral liver extracts achieve similar results to those obtained by folic acid is not so simple of explanation. The folic acid content of the effective daily dose of such preparations is stated to be considerably less than 1 mg, a quantity which by itself is unlikely to produce the maximal haemopoietic responses which we regularly obtained. Such oral liver preparations, however, contain, in addition to folic acid, L.F., other members of the vitamin B complex, and amino-acids. It may be found in the future that the combination of folic acid and parenteral or oral liver therapy will be effective in doses which, when given individually, are inactive. That substances other than folic acid and L.F. may be required to bring blood formation completely back to the final stage of normoblastic blood formation is suggested by our findings that some cases of the sprue syndrome and idiopathic refractory megaloblastic anaemia continue to have a macrocytic anaemia and a primitive type of normoblastic marrow, despite continued administration of potent parenteral liver extracts and folic acid. In some of these cases, but by no means all, a final and complete transformation to normality was secured by the addition of proteolysed liver (hepamino).

Folic acid is a vitamin, a member of the B₁₂ complex. Hence it is not unreasonable to suppose that the general principles covering the therapeutic administration of vitamins are also applicable to folic acid. These principles may be summarized as follows.

1 A beneficial result will occur only if the body is deficient in the vitamin. Attention is drawn to the dramatic effect of ineurine in beriberi and to its complete failure to influence the course of infective polyneuritis.

2 When an individual has a sufficiency of a vitamin the giving of excessive amounts is valueless and wasteful. It is justifiable during the initial period of treatment of a vitamin deficiency disease to give from 10 to 20 times the amount required for normal maintenance purposes in order to replace the body's depleted stores as rapidly as possible. Thereafter the daily amount prescribed should be reduced to the accepted optimal daily requirements and be given where possible in the form of natural foods.

3 In vitamin deficiency disease replacement therapy produces a therapeutic result rapidly. The beneficial effects will be obvious within a few days and sometimes within a few hours. Failure to achieve therapeutic success within one or two weeks accordingly indicates a mistaken diagnosis, and the continued administration of the vitamin is an expensive and unwarranted procedure.

If these principles are applied to folic acid a rational basis for treatment will be forthcoming. It is believed that the daily requirement of folic acid is in the neighbourhood of 0.5-1 mg, and that normal individuals partaking of an average mixed diet can easily obtain this amount from their food. The same remarks apply to patients with Addisonian pernicious anaemia. Since, however, such patients are unable to obtain free folic acid from the conjugated form in food they require injections of liver extract. Provided they are taking a satisfactory mixed diet the addition of free folic acid will not be required so long as they are receiving adequate parenteral liver therapy.

Since it has been shown by ourselves and by Spies and Stone (1947) that folic acid is unable to prevent or cure subacute combined degeneration of the cord, folic acid cannot be recommended as the sole therapeutic agent for maintenance treatment in pernicious anaemia or when neurological changes are present. It may be used as a temporary measure in the initial treatment of pernicious anaemia and in patients sensitive to liver extracts awaiting desensitization. The suggested dose is 5-10 mg daily by mouth. Until the factor required for the maintenance of the integrity of the nervous system is isolated and combined with folic acid, parenteral liver therapy must continue to be the accepted routine method of treatment of pernicious anaemia.

Since subacute combined degeneration of the cord very rarely develops in nutritional megaloblastic anaemia, pernicious (megaloblastic) anaemia of pregnancy, idiopathic refractory megaloblastic anaemia, or the sprue syndrome, folic acid can be safely advocated both for initial and for maintenance therapy in doses of 5-10 mg daily. In the first two diseases the administration of folic acid can be stopped when the blood count is normal provided a satisfactory well-balanced diet is eaten. In the third disease maintenance treatment (suggested dose 5 mg daily) will be required for life. In the sprue syndrome maintenance requirements will vary in individual cases according to the course of the disease. If the blood level or blood picture in patients with any of the above diseases fails to return quantitatively and qualitatively to normal a supplement of oral liver extract or proteolysed liver (1 oz daily) should be given. There is sound evidence for the belief that for the treatment of any megaloblastic anaemia quantities of folic acid in excess of 10 mg daily are unnecessary and

wasteful. Moreover, if haematological and clinical improvement does not occur within two weeks it can be assumed that the disorder is not due to deficiency of folic acid and that continued administration of the vitamin is contraindicated.

Summary

An account is given of the results of treatment with folic acid of (a) 16 cases of pernicious anaemia, (b) 5 cases of refractory megaloblastic anaemia, (c) 10 cases of the sprue syndrome, (d) 3 cases of subacute combined degeneration of the cord, (e) 5 cases of aplastic and hypoplastic anaemia, (f) 9 cases of leucopenia, (g) 9 cases of thrombocytopenia, and (h) 5 cases of ulcerative colitis.

A haemopoietic response was obtained only in the cases in which the bone marrow was megaloblastic—i.e., cases in groups a, b and c.

No therapeutic changes were obtained in cases of aplastic anaemia, leucopenia, or thrombocytopenia.

In the sprue syndrome folic acid controlled the diarrhoea and produced general clinical improvement in adult patients suffering from tropical sprue and idiopathic steatorrhoea. Folic acid by itself seldom restored the blood level or blood picture to normal. In none of the cases of coeliac disease was any haematological or clinical improvement noted.

The clinical and sigmoidoscopic appearances in 5 cases of idiopathic ulcerative colitis were unaffected by folic acid therapy.

The rationale of the action of folic acid and the principles underlying its therapeutic administration are discussed.

The New Health Club in which the late Sir William Arbuthnot Lane was a prominent figure, revived its activities after wartime dormancy on March 19 with a tea time *causerie* at which Sir Albert Howard for many years imperial economic botanist to the Government of India, gave an address on "Soil, Food, and Health". Sir Albert Howard has had a large experience of the food habits of primitive peoples which enable them to withstand some of the ills besetting civilization. He admitted that in a community such as ours it was not possible to revert to an entirely primitive dietary: the easiest thing to concentrate upon, he said, was bread. It was possible even in London to obtain properly grown wheat—properly grown meaning the cultivation of the soil having regard to its natural properties and without dependence on artificial manures. Such wheat, roughly ground and made into bread or porridge gave a perfect food quite different from anything ordinarily obtainable in the shops. It was now open for anyone to take out a licence to buy properly grown wheat from the farmer mill it on his own premises and make his own bread. A breakfast cup of roughly ground wheat soaked in milk and eaten raw was extraordinarily satisfying and beginning the day with such a meal he himself could go on happily without troubling about food until evening. It was not quantity that mattered but absence of sophistication. He hoped to see in England a new type of baker in which something quite different from ordinary flour was used, the wheat going in at one end and being ground out roughly, with no separation of bran. If the product was put straight into bread the impurities in quality obtained was almost unbelievable.

THE PHYSICAL HEALTH OF CHILDREN ATTENDING DAY NURSERIES

A REPORT TO THE DAY NURSERIES COMMITTEE OF THE MEDICAL WOMEN'S FEDERATION

BY

MARGARET E. McLAUGHLIN, M.B., B.S., D.C.H.

PART I

Aim and Method of Investigation

In 1944–5 an investigation was made under the auspices of the Medical Women's Federation to obtain data concerning the effect of life in wartime day nurseries on the physical health of children under 5 years old. The investigation was made in two parts. In the first part a comparison was made of children attending day nurseries and children attending welfare centres, and the records were based on the results of a single examination of each child by 73 medical officers in different parts of the country in the course of their normal work. The results of this section of the investigation have been published already (*Journal*, Aug 17, 1946, p. 217).

The present report describes the results of the second part of the investigation, carried out by me, this has been a comparison over a period of twelve months in 1944–5 of a group of children attending Ministry of Health wartime day nurseries in Birmingham with a control group of children living in their own homes. Periodic examinations of the children in both groups were made during the survey.

Selection of Clinical Material

The nursery group of children was composed of the entire population of eight Ministry of Health wartime day nurseries in different parts of the city, thus various social and economic groups were represented. The nurseries were open from 7 a.m. to 7 p.m. for 5½ to 6 days a week and nearly all the children spent their whole day in the nursery, as their mothers were mostly engaged on full-time war work. Each nursery was under the care of a fully trained nurse with a staff of trained and student nursery nurses and nursery assistants and a certificated or non-certificated nursery teacher. The approved complement of staff, excluding domestic staff, was one nurse to four children but owing to the wartime conditions this was not always attained. Each nursery accommodated from 48–60 children aged 0–5 years (one nursery accommodated 80 children). The premises ranged from specially constructed one story buildings of a semi-permanent character to converted old houses or portions of the premises of infant welfare centres. The children were provided with three full meals or two meals and mid-morning lunch every day. These meals, which were generous and well planned, were provided without the surrender of any of the children's own ration coupons, which were thus still available for their use at home. The rationed food which could be obtained for children attending nurseries was thus nearly double that available to children having all their meals at home—i.e., they could have twice the quantity of meat, butter, bacon, eggs, cheese, etc. An isolation room was provided in each nursery, and all children were examined each morning on arrival by a senior member of the staff admission being refused to children obviously ill and those with infectious skin diseases. Children with colds could not, however, be excluded as a routine measure. A child-welfare medical officer was available on call for any sick child and routine medical inspections of all the children were periodically made. A medical certificate of fitness was necessary before admission or readmission to a nursery.

The control group of children was composed of those living at home and attending no nursery school or class for young children. They were classified into eight subgroups each drawn from the same residential area as one of the eight nurseries chosen for the survey. The children were selected at random from the health visitors' official lists of all those under 5 living

in the district. Apart from choosing children to give an age distribution similar to that in the corresponding nursery the children in the home group were picked entirely at random to ensure a representative sample of all types of population in the district. The selected children were then visited at home by health visitors from the nearest infant welfare centre the purpose of the survey was explained to the mothers and a request was made that they would bring their children to the centres periodically for examination. Subsequently appointments were given by post. Naturally a considerable number of the children were already attending the centres, but it is a tribute to the efforts and eloquence of the health visitors that such a good response was obtained from mothers who had never previously made use of the facilities of the welfare centres. To allow for the inevitable defaulting 40% more children were selected in the home group than attended the nurseries.

Comparability of Nursery and Home Groups.—Every effort was made as explained above, to ensure that the children in the home group had so far as possible similar social and economic backgrounds to those of the nursery group. It was recognized however that many factors affected the attendances and influenced the economic status of children in both home and nursery groups. Thus there was a distinctly higher proportion of illegitimate children and children from homes broken up by desertion separation, or death in the nursery group than in the home group. In the nurseries 8% were illegitimate and 4.6% from broken homes, in the home group 1.8% were illegitimate and 1.4% from broken homes. In estimating the importance of this fact it must be remembered that the infant mortality rate among illegitimate babies in Birmingham approximates to the rate for legitimate babies, and in one recent year was actually lower. There are special arrangements for the care of illegitimate children in the city, and the morbidity rate among them may be reasonably assumed to show similar results. Whether economic status was higher among day nursery families or among families of the home group is not known. Economic need was certainly one cause leading mothers to seek paid work and place their children in nurseries, and the family income was markedly increased by the mother's whole time earnings. On the other hand, the home group contained all those families with more than two young children who were thus not eligible for admission to the nurseries and whose mothers were unable therefore, to seek whole-time paid work and it is notorious that as the number of children increases so does the incidence of poverty. The extra allowance of foodstuffs of animal origin available to children attending day nurseries must also be taken into account when considering economic status and nutrition in the two groups. Reported attendances were more likely in the home group if a child was ailing and also if a mother was over-anxious. A strong financial inducement existed for mothers of nursery children to ensure their regular attendance but, on the other hand mothers of nursery children were instructed not to bring them if they had coughs bronchitis etc., and there were no such injunctions for children of the home group.

No definite conclusions can be drawn from these points as it is impossible to assess the relative effects of all these factors on the results of the survey.

Method of Observation and Examination

Every child was examined at intervals of eight weeks. The investigation lasted 12 months (November–October) and the majority of the children attended for the first time in November and December. Replacements were made in each group throughout the year—to maintain numbers as far as possible. Each nursery was visited on the same day as the corresponding welfare centre. All the examinations were carried out by me. At each visit a full physical examination was made with the child stripped, and a full history taken of previous illnesses. The history was obtained direct from the mother in the home group and usually indirectly from the mother through the matron in the nursery group. Any account of infectious fevers was verified by reference to private doctor or hospital or by full inquiry into the clinical features of the illness. All

physical findings were recorded, including normal ones. Lastly, each child was weighed on checked scales of the pan-and-weights type. The numerical details of the investigation are given in Table I.

TABLE I—Numerical Details of Investigation

	Nurseries	Home Group	Total No
Total number of children in survey	557	641	1 198
Boys	275	302	
Girls	282	339	
Total number of examinations	1 734	1 516	3,250
Boys	857	709	1 566
Girls	877	807	1 684
Total examined twice or more	432	409	841
Total examined once only	125 (22.4%)	232 (36.2%)	357
(a) Actual examinations per child	3.1	2.4	
(b) Excluding single examinations	3.7	3.1	
Age distribution of examinations of children in survey			
(1) Under 1 year { 0–6 mths	49 (2.8%)	58 (3.8%)	
6–12	149 (8.5%)	186 (12.3%)	
(2) 1–2 years { 12–18 mths	186 (10.7%)	203 (13.4%)	
18–24	204 (11.8%)	252 (16.7%)	
(3) 2–3	431 (24.9%)	328 (21.6%)	
(4) 3–4	379 (21.9%)	293 (19.3%)	
(5) 4–5	336 (19.4%)	196 (12.9%)	

Physical Findings Comparison between Nursery and Home Groups

In the following tables the percentage figures are based, except where otherwise stated, on the total number of examinations made in each group. The data on infectious fevers, however, are based on the total number of examinations only of children attending more than once, since data for infectious fevers were obtained from histories of illnesses between the current and previous examinations. With this exception all figures are based on the results of 1,734 examinations of 557 nursery children and 1,516 examinations of 641 home children.

1 General Condition

The clinical impression of general condition was recorded at each examination in one of four grades: (a) *Very good*—where nutrition, growth, and posture were excellent and no signs of respiratory tract or other infection were present, beyond perhaps a very slight head cold. (b) *Good*—where nutrition growth and posture were satisfactory but not outstanding, or where signs of respiratory tract or other infection of more than slight degree were present. (c) *Fair*—where nutrition posture or growth was considerably subnormal (due to present or past disease) or where fairly severe respiratory or other infections were present. (d) *Poor*—where growth and nutrition were grossly subnormal, or with signs of severe past or present infection or other disease.

Results.—Table II compares the percentages in nursery and home groups of examinations where the general condition was recorded as good or very good, thus for a child attending on three occasions the general condition was recorded three times.

For all ages together, boys and girls of the home group had a higher percentage whose general condition was very good or good, the difference between nursery and home groups being significant for both boys and girls. The children were subdivided into age groups. Under 2 years of age the girls in the home group had a higher percentage whose condition was very good or good, and the differences from the nursery group were significant in all four age subdivisions. The boys under 2 years old in the home group had a higher percentage in the very good or good category, the difference from the boys under 2 in the nursery group being significant in two of the four age subdivisions. Over 2 years old there were no significant differences between home and nursery groups, but in four out of six age subdivisions (boys and girls) the nursery group had a slightly higher percentage of examinations of children in good or very good condition.

TABLE II—Percentages of Examinations where General Condition was Very Good or Good

Age	Group	Boys	Girls

2 Condition of Tonsils

Tonsillar enlargement was recorded as of slight, moderate, and gross degrees. In addition the incidence of tonsillectomy was recorded. Acute or subacute tonsillitis was not included in this section, which refers only to chronic conditions.

Results (Table III)—(a) The incidence of slight and moderate tonsillar enlargement was at all ages considerably higher in the nursery group than in the home group among both boys and girls. (b) The incidence of gross tonsillar enlargement was also significantly higher in the nursery group than in the home group for all ages together, among boys and girls. (All degrees of tonsillar enlargement together were more than twice as frequent in the nursery boys than in the home group. Among girls they were nearly four times more frequent in the nursery

group than in the home group) (c) The incidence of tonsillectomy was higher in the nursery group. No child under 2 years old in either group had had the tonsils removed. Between 2 and 5 years of age 5.1% of the boys and 2% of the girls in the nursery group had had the tonsils removed, in the home group the figures were 0.8% for boys and 0.9% for girls. The difference was significant for the boys, but the difference for the girls might have arisen by chance.

3 Enlargement of Cervical Glands

This was recorded as (a) slight or moderate, and (b) gross. The former category included all glands distinctly palpable at the angle of the jaw, and in the majority of cases only the anterior cervical group of glands was involved. All results refer to chronic enlargements, those cases occurring, for example, during a subacute infection being excluded.

Results (Table IV)—There was a much higher percentage of enlarged cervical glands in the nursery group, among both boys and girls. (a) For slight and moderate degrees of enlargement there were significantly higher rates in the nursery group for all ages together (0-5) and in 5 out of 7 of the individual age groups both for boys and girls. (b) For gross degrees of

* Significant differences

enlargement there was a significantly higher rate among nursery boys and girls at all ages combined (0-5), but (c) the proportion of grossly enlarged glands to all enlarged glands was slightly greater in the home group. In the nursery group 13.8% of all boys with enlarged glands and 10.3% of all girls with enlarged glands were recorded as having glands grossly enlarged, the corresponding figures for the home group were 15.4% for boys and 13.3% for girls. Cervical gland enlargement was however, about 2½ times as common in the nursery group as in the home group.

4 Nasopharyngeal Infections

These were recorded in two categories (a) subacute and acute (b) chronic. The former included cases of subacute coryza, laryngitis, nasopharyngitis, etc., actually observed at examination, the latter included cases of chronic nasal discharge, sinusitis, adenoid enlargement, etc., in which the chronic nature of the condition was confirmed either by repeated examination or history.

Results (Tables V and VI)—(a) Subacute and acute nasopharyngeal infections—For all ages together (0-5) there was a higher incidence in the nursery group but the difference was significant only among boys, that for girls being within the limits of chance occurrence. **(b) Chronic nasopharyngeal infections**—The incidence was eight times as great in the nursery

developed mouth breathing tended to do so at a slightly earlier age in the nursery group than in the home group

5 Bronchitis

Only those showing physical signs of bronchitis at examination were included. As was expected the highest incidence was in infants under 2 years old.

Results (Table VII)—For all ages together (0-5) the incidence was about twice as large in the nursery group, the difference between nursery and home groups being statistically significant for both boys and girls.

[Part II with references, will appear in our next issue]

The Medical Advisory Committee (Scotland), chairman Sir John Fraser, has now submitted its report on laboratory services to the Secretary of State (H.M. Stationery Office, 2d). In considering whether the laboratory service should cover all branches of laboratory medicine or exclude public health work, the committee chose the former course. Certain allied services would be incorporated in the laboratory service, in particular a specialist service for conducting medico-legal necropsies and a service for the bacteriological examination of milk, food, and water supplies. "The service we recommend would be a national one, under central administration with a regional grouping of laboratories centred on the four university medical schools with appropriate arrangements for Inverness and the Northern Counties. Each regional group of laboratories would represent a self-contained section of the service but this would not exclude inter-regional co-operation and mutual assistance where necessary, and the whole time members of the professional and technical staffs of the service would be interchangeable among laboratories." It is assumed that the Director of Health for Scotland will administer the service. In the first place as many as possible existing laboratory resources will be utilized. A central laboratory organization would be centred in the university medical school, teaching hospitals, and public health department, and district laboratories would be established in association with either a general or infectious diseases hospital. As regards the training of staff the committee recommend that there should be a period of five years postgraduate training before recognition as a specialist in laboratory medicine is granted. In the medical schools aspirants to this branch might be encouraged to take courses for combined degrees in medicine and honours in science. The first year of training should be spent as house physician and house surgeon, six months of this year possibly being spent in an infectious diseases hospital. The committee points out that in certain parts of Scotland laboratory services must be mobile and it recommends that mobile units be established at various centres.

POTASSIUM THIOCYANATE IN THE TREATMENT OF HYPERTENSION

BY

GEOFFREY WATKINSON, MD, M.R.C.P.

*Seniorly Medical Chief Assistant St Bartholomew's Hospital
Fl-Lieut Medical Specialist R.A.F.*

AND

GEOFFREY EVANS, MD, F.R.C.P.

Emeritus Physician St Bartholomew's Hospital

Potassium thiocyanate has been used in the treatment of hypertension since Treupel and Edinger (1900) and, later, Pauli (1903) recommended it. In spite of considerable clinical experience of its use there is still some doubt of its value. The risk of toxic symptoms is its main drawback. Recent American opinion on the subject expresses this conflict of opinion. Thus Fishberg (1944) writes "I have seen little, if any, actual benefit to the patient, and, in view of the risk of toxic symptoms, have abandoned the use of thiocyanate", whereas Page and Corcoran (1945) conclude "a review on the subject with the statement, 'Yet long experience has shown that, with control of the thiocyanate level in the blood, dangerous toxic manifestations will be rare—sufficiently rare to justify its intelligent use'". They also report that "most evidence indicates that thiocyanate is useful in the management of many patients with hypertension".

We submit that the reasons for this difference of opinion are (1) the narrow margin on occasion between the therapeutic and the toxic dose of the drug, as also the fact that a toxic rash may appear when the drug concentration in the blood is at a low level, and (2) the coincident arteriosclerotic disease is not as yet either recognized or understood. It is our object to present some further observations on the use of potassium thiocyanate in patients with hypertension, and especially to attempt to correlate our results with the phase of the underlying arteriosclerotic disease.

Outline of Treatment

A constant serum thiocyanate concentration of between 5 and 12 mg per 100 ml of blood is the objective. A concentration or level of 15 mg may be toxic, and a level of 40 mg is potentially fatal. Barker (1936) recommends that the initial level to be attained should be 5–8 mg, and that if there is no clinical improvement the dose should be increased until a level of 8–12 mg is reached. He states that some cases respond to the higher dosage, though they have not shown any improvement at the lower concentration. We have been able to confirm this observation in several instances; nevertheless, our usual practice is to work at the lower concentration of 5–8 mg. The method of serum thiocyanate estimation used is a modification of Ravin's (1940) method. A comparator disk was specially prepared for our use by Messrs Tintometer Ltd.

The dosage is that recommended by Barker (1936), and used by D Silva and Evans (1944). The initial dose is potassium thiocyanate 0.1 g, chloroform water to 1/2 oz (14 ml). It is given with water three times daily after food and amounts to 2.1 g weekly. If it causes nausea or other symptoms of gastric irritation it is taken with food instead of after. The drug may be given in enteric-coated capsules if it causes nausea. Repeated estimations of serum thiocyanate are essential, at first weekly, then at two-weekly and monthly intervals and later at three- and six-monthly intervals. The amount of potassium thiocyanate necessary to maintain the required concentration in the blood varies

widely in different individuals. It may be as low as 0.8 g or as high as 4.2 g a week.

The patient is best treated at rest in bed for the first fortnight or three weeks, with such symptomatic treatment as is required to provide peaceful sleep, regulation of bowel function, suitable diet, and so on. The effect of the treatment on the patient's well-being and blood pressure is noted. After four to ten days the potassium thiocyanate is given, if the necessary indications for its use are still present, in a dose of 2.1 g weekly. At the end of one week's treatment the serum thiocyanate concentration is estimated. Cases are then divided into four groups.

1. *Serum Level of 4 mg or less per 100 ml of Blood*—The weekly dose is increased to 2.4 g. A second estimation must be done after a week on this increased dosage, because it occasionally happens that there is a rapid increase of thiocyanate concentration in the second week of treatment. Thereafter the dose is increased or decreased by 0.4 g weekly until a satisfactory level is maintained.

2. *Serum Level 5–7 mg*—The weekly dose remains at 2.1 g. The serum thiocyanate estimation is repeated in a week.

3. *Serum Level 7–10 mg*—The weekly dose is reduced to 1.4 g, and the serum thiocyanate estimation is repeated at the end of a further week.

4. *Serum Level 12 mg or Over*—Withhold the drug for 14 days, and repeat the serum thiocyanate estimation. Occasionally a high serum concentration may persist for three weeks after the drug is discontinued. According to result the drug is given again, probably at the rate of 1.2 g weekly. Subsequent dosage depends on experience gained in this first fortnight of treatment, and the dose of potassium thiocyanate remains the same during the third week of treatment, or is increased or decreased by 0.4 g weekly according to indications provided by the second serum thiocyanate estimation. The dose should never be increased at one time by more than 0.4 g weekly. A third serum estimation is made at the end of a further week or fortnight, and after this it may be possible to make the interval a fortnight or a month.

Control of Treatment—The quantity of potassium thiocyanate administered should be based on serum estimations. Blood-pressure readings are no criterion of dosage. A brief written record must be kept of the potassium thiocyanate intake, the serum thiocyanate concentration, and the blood-pressure readings, and a statement made as to symptoms, in order that the practitioner may have a bird's-eye view of the treatment of the case, which is likely to extend over months or years.

Indications—(1) Treatment with potassium thiocyanate is indicated for the relief of symptoms due to hypertension, especially headache and giddiness, when rest in bed and other conservative symptomatic treatment have failed. (2) Potassium thiocyanate may be effective when surgical treatment has failed. We have confirmed the observation of Page and Corcoran that, prior to sympathectomy, the drug may be a good pre-operative agent in minimizing the hypotensive crisis that sometimes follows the operation. (3) It is also indicated for patients whose diastolic pressure is 130 mm Hg or over and who have not responded to treatment on conservative lines.

Contraindications—Severe renal damage is generally regarded as a contraindication. In these cases the drug is apt to accumulate rapidly and may soon reach a toxic level. Provided frequent serum thiocyanate estimations are made, it can, however, be safely given, and occasionally some benefit is obtained. Myocardial disease, anginal pain, and heart failure, though not actual contraindications to the careful use of thiocyanate in patients with hypertension, are conditions in which the drug is of little value. The danger of toxic effects is said to increase with age and Vassie (1941) has advised that the drug should not be given to patients over 60 years of age. We have not confirmed

this observation. In our present series the 15 patients over 60 years old showed no particular intolerance to the drug.

Material and Clinical Observations

The cases reviewed here consist of 60 patients with persistent hypertension, and include most of the cases of hypertension admitted to an E.M.S. medical unit (Cell Barnes Hospital) during four years.

A detailed history was obtained of every case. A careful clinical examination was made and repeated blood-pressure readings taken. It is common knowledge that appreciable variations of blood pressure may occur both in normal and in hypertensive individuals (Allen, 1942). On this account the pressures were recorded in the forenoon, with the patient at rest, and the patient was kept under observation for a week before thiocyanate treatment was started. By this means daily fluctuations of blood pressure and the effect of rest in bed were noted. The further investigation of a patient also included a microscopical examination of the urinary deposit, renal function tests, and intravenous pyelography. In only one of the 60 cases was unilateral renal disease discovered—namely, a tuberculous kidney of three years' standing, associated with severe malignant hypertension in a young woman aged 22. An electrocardiogram was also done, and in many of the very ill patients myocardial disease was disclosed.

Classification

The crux of the problem of hypertension on which both the response to therapy and the prognosis depend is the opinion based on the patient's history and clinical examination as to whether the disease is active or quiescent. Whereas Moschowitz (1945), for example, regards arteriosclerosis as a progressive and irreversible condition, our conception is of an arteriosclerotic process characterized by periods of activity and periods of quiescence. To make this matter clear, though it is not completely established as yet by factual knowledge, we postulate a functional equivalent in terms of vascular spasm and a structural equivalent which is arteriosclerosis. According to this conception a widespread arteriolar constriction in the systemic circulation will cause hypertension, and local vascular spasm may be responsible for cerebral, cardiac, renal, and other symptoms. Such functional disorders of vascular tone are not necessarily permanent or progressive, but when there is a coincident or resultant change in structure of the vessel walls an irreversible stage in the progress of the disease is registered. From this point of view it will be understood that persistent hypertension is not necessarily a sign of active and progressive disease unless the diastolic pressure is high—namely, at a level of 130 mm Hg or over. It is our experience that persistent diastolic pressures of this order are generally an indication of progressive disease. The evidence of a change in vascular structure and active arteriosclerotic disease is looked for in the presence of haemorrhages which, apart from frank haemorrhage such as epistaxis, haemoptysis, haematemesis, melaena, and menorrhagia, include retinal haemorrhages and microscopical haematuria.

Other evidence of an active phase of arteriosclerotic disease is to be found in electrocardiographic evidence of myocardial damage, in venous and arterial thromboses, and in the presence of renal damage such as allows of the diagnosis of malignant hypertension. Thus the disease may be quiescent in a patient who has symptomless hypertension and a blood pressure which remains fairly steady at a level of 210 mm Hg systolic and 100 mm Hg diastolic, but a phase of activity and progressive disease will be recognized by increasing hypertension, the appearance of

new symptoms such as headache or giddiness, especially by the appearance of microscopical haematuria and retinal haemorrhages, and perhaps papilloedema. By these signs of disease benign hypertension is recognized as passing into the malignant phase. In some cases, however, a quiescent phase may follow and the retinal haemorrhages and microscopical haematuria may disappear, less commonly the disks become normal in outline. Although the hypertension persists the disease may become quiescent, and a balance of health may be restored and last for a number of years (Evans, 1943).

The cases were classified in four groups, and the diagnosis was made after completing the routine detailed examination already described.

Group I Benign Hypertension Quiescent Phase—These patients had a persistently raised blood pressure but retinopathy showed only retinal arteriosclerosis without haemorrhages or exudate, and there was no microscopical haematuria.

Group II Benign Hypertension Active Phase—In these patients the arteriosclerotic process was judged to be active by the presence of microscopical haematuria, retinal haemorrhages, wide fluctuations of blood pressure, symptoms of major significance, or other signs of active disease already described.

Group III Malignant Hypertension—In this group there was severe hypertension (the diastolic pressure usually exceeding 130 mm Hg), impaired renal function, and papilloedema.

Group IV Renal Hypertension—Six patients with hypertensive symptoms were treated, in three the underlying pathology was found to be chronic nephritis, in two the sequelae of a toxæmia of pregnancy, and in one due to polycystic disease of the kidneys.

Results of Treatment

The criteria by which the result of potassium thiocyanate therapy was assessed were its effect on blood pressure and on symptoms. The patient was put to bed for a week and daily blood-pressure readings were taken. Thiocyanate was given only to patients in whom the blood pressure remained persistently raised or in whom symptoms persisted in spite of rest in bed and symptomatic treatment. The lowest pressure recorded in the first week was taken as the base line reading. The drug was then administered until an adequate serum level had been maintained for three weeks, when the average blood pressure recorded in the third week was taken as the final reading. Most American writers regard falls of 15% in systolic and diastolic pressures as a "good" effect and 10% as a "fair" effect. We have taken a more conservative figure—namely, 40 mm Hg systolic and 20 mm Hg diastolic—as significant reductions in pressure. The fall in pressure recorded is therefore additional to that obtained by rest in bed. The symptomatic effect was assessed by replies to direct questions the symptom being "cured," "improved," or "unaffected."

The results are summarized in the accompanying table. By "immediate effects" is meant the condition of the patient on discharge from hospital. Under "late effects" the condition is given of 42 subjects of hypertension who received adequate doses of the drug for periods of more than a year. One patient has been taking the drug for more than three years, nine for more than two years, and the remainder for more than a year. Twelve patients have died within the period of observation.

Discussion of Results

As will be seen from the table the drug's effects can be correlated with the disease process. Its immediate effects were most pronounced in cases of the benign quiescent group, where almost three-quarters showed significant falls in blood pressure and obtained complete symptomatic relief. In the benign active group about two thirds of the

cases responded to thiocyanate—a smaller proportion than in the quiescent group. In the malignant phase potassium thiocyanate is of little value, but even in these severe cases symptomatic relief may be obtained and, rarely, the progress of the disease may be temporarily stayed.

Six cases of renal hypertension were treated. Symptomatic relief was obtained in four, and in two there was a significant fall in blood pressure.

Of the 60 cases reviewed in this paper 62% obtained complete symptomatic relief and 56% showed significant falls in blood pressure. These results as to immediate

Table Summarizing the Effect of Administration of Potassium Thiocyanate to 60 Cases of Hypertension in Varying Phases

Classification	Immediate Effects			Late Effects			Remarks
	Number Treated	Number Obtaining Complete Symptomatic Relief	Number Showing Significant Falls in B.P.	Number Treated	Number Obtaining Complete Symptomatic Relief	Number Showing Significant Falls in B.P.	
Benign quiescent hypertension	23	17	16	15	8	9	No deaths
Benign active hypertension	21	12	13	13	6	6	4 deaths, all due to coronary thrombosis
Malignant hypertension	10	4	3	8	—	2	5 deaths: 3 in 1st year, 1 in 2nd, 1 in 3rd. All due to uraemia
Renal hypertension	6	4	2	6	3	1	3 deaths, all due to uraemia
Total Percentage	60	37/62%	34/56%	42	17/40%	18/43%	

effect of thiocyanate therapy are similar to those obtained by Wald *et al.* (1939)—246 cases. As to its late effect, 42 patients received adequate treatment for more than one year. Of 15 patients with benign quiescent hypertension nine remained throughout the period of observation with a significant fall in blood pressure and relief of symptoms. Of 13 patients with benign active hypertension six maintained a significant fall in blood pressure with relief of symptoms.

There is not as yet good evidence that potassium thiocyanate controls the activity or progress of arteriosclerotic disease, although it is our opinion that it has had this effect in certain cases. There is clear evidence that the disease may be progressive in spite of symptomatic relief and some measure of control of blood pressure as a result of continued use of the drug. In the group composed of 23 patients with benign quiescent hypertension there were no deaths but in the group composed of 21 patients with benign active hypertension there were four deaths due to coronary thrombosis. The occurrence of four fatal cases with benign active hypertension and none with benign quiescent hypertension, together with the fact that a rather smaller proportion of the benign active hypertensive group than of the benign quiescent hypertensive group were benefited by the treatment, justifies the division of benign hypertension into these two groups. It also suggests that potassium thiocyanate is not very effective in preventing progress of the disease in benign active hypertension. Further evidence in support of this view of the limited value of potassium thiocyanate is the clinical course of three cases in which the blood pressure was well controlled. One patient whose blood pressure was 160/80 developed a retinal thrombosis; another developed retinal haemorrhages; a third in spite of a fair measure of blood-pressure control continued to suffer from headaches and paroxysmal hypertension although taking potassium thiocyanate. On

the other hand, it is interesting that symptomatic relief may be maintained in spite of continued progress of arteriosclerotic disease. Thus of five fatal cases with malignant hypertension two were relieved of headache until death ensued.

With regard to the ten patients with malignant hypertension, there was immediate relief of symptoms in four, together with a real improvement in the general condition. One patient, a man aged 44, was dying of uraemia on admission to hospital. He made a remarkable recovery, became symptom-free, and returned to work. He remained at work for 20 months, and died suddenly of uraemia two years after his first admission to hospital. Six cases of renal hypertension have been treated, with symptomatic relief in four. This confirms the observation of Kurtz *et al.* (1941) that potassium thiocyanate may be useful in chronic nephritis. It does not seem to prolong life in this disease.

Of the 42 patients treated for more than a year a significant fall in blood pressure was obtained in 18 and symptomatic relief in 17.

In general terms these patients have been maintained on a serum thiocyanate level of 4 to 8 mg per 100 ml. It is possible that better results might be achieved by a serum thiocyanate concentration of 8 to 12 mg.

The drug is most effective in its relief of headache, dizziness, and vertigo. Improvement in vision was observed, but its effect in this respect is difficult to assess. Mental confusion was cleared in one case. Malaise and asthenia were relieved in several patients. The drug is much less effective in its relief of cardiac symptoms. Of six patients with angina, only one improved, four were unaffected, and one was worse. It has no effect on the sensation of palpitations. Three patients with intermittent claudication and hypertension were not improved in respect of their pain.

Toxic Effects

Symptoms of intolerance are a rash, malaise, asthenia, loss of appetite, nausea, indigestion, pains in the limbs, and impotence. The significant symptoms are a rash, excessive tiredness and nausea. The rash varies considerably in appearance and distribution, characteristically it is a dull-red maculo-papular rash, somewhat irritating, and ending by scaling. The macules may be sharply defined and are followed by pigmentation, which ultimately fades out. A common distribution is on the flexor aspects of the wrists and forearms, on the lower third of the legs, or on the front and inner aspect of the thighs. It may be on the extensor aspect of the extremities and on the neck and trunk. It may be urticarial or haemorrhagic. It may appear with a serum thiocyanate concentration as low as 4 mg or even 3 mg per 100 ml. After its disappearance resumption of thiocyanate administration in some cases is not followed by a reappearance of the rash. Some degree of tiredness in the early stages of treatment is not a contraindication to continuing the treatment. If the asthenia is considerable or if tiredness appears for the first time at a later stage in the treatment, the serum thiocyanate concentration should be checked at once. Indigestion in the early stages of treatment is remedied by giving the thiocyanate with food instead of after food. Indigestion and nausea appearing later in the treatment are probably an indication of overdosage; the administration of thiocyanate is therefore stopped and the serum thiocyanate estimated at once. There are other uncommon symptoms of thiocyanate intolerance or overdosage, including perhaps thrombophlebitis. An individual taking thiocyanate consequently needs to be under medical observation.

In the present series skin rashes have occurred in six patients in four the drug was given again without causing reappearance of the rash, and in two the rash reappeared and the thiocyanate had to be stopped. Koffler and Freireich (1944) have reported femoral thrombophlebitis in four of a series of 40 cases treated, and observed that the lesion tended to recur if the drug was repeated. In the present series this complication has occurred twice. In a larger series of other cases under the observation of one of us it has not occurred at all. Goitre is reported to have followed the long-continued administration of potassium thiocyanate. Wald *et al* (1939) report 11 cases in 246 patients treated. We have not seen this complication. Our opinion is that, apart from skin rashes which may occur at low serum thiocyanate concentrations, toxic effects are uncommon provided that the dosage of the drug is properly controlled. The necessity for close control, especially in the early stages of thiocyanate therapy during which the adequate maintenance dose is being ascertained, cannot be over-emphasized.

It is said that thiocyanate therapy may be responsible for retinal, cerebral, and coronary thrombosis, but this opinion takes no account of the fact that a proportion of patients with persistent hypertension are suffering from active arteriosclerotic disease and that this disease is the cause, or may be the cause, of thrombotic phenomena occurring during the administration of thiocyanate.

Summary

An attempt has been made to assess the value of thiocyanate therapy in hypertension. A scheme of dosage has been given together with indications for treatment. Patients with hypertension have been classified according to phases and types of hypertensive disease. Taking the cases as a whole, symptomatic relief and a significant fall in blood pressure were observed in roughly 60% of the cases. The further observation of 42 patients shows that the effect of thiocyanate therapy can be correlated with the phases of the arteriosclerotic process, and that whereas symptomatic relief is given and blood pressure reduction is maintained in approximately 40% of the cases, the continued administration of potassium thiocyanate does not prevent, in individual cases at least, the continued progress of arteriosclerotic disease.

The Minister of Food has issued a General Licence (S R & O, 1947, No 595) under the Food Rationing (General Provisions) Order, 1946, which regularizes the arrangements for the supply of glucose barley sugar, free of personal points rationing to persons for whom it is prescribed by registered medical practitioners. It prescribes the maximum quantity which can be supplied and provides for prescriptions covering a certain number of repeat purchases. Ration free sales to the public can be made only by registered pharmacists and the responsibility for checking the prescriptions is placed upon them and manufacturers. The licence indicates how registered pharmacists may obtain glucose barley sugar from manufacturers to fulfil prescriptions or to replace stocks sold ration free. The Order came into operation on April 6.

AUTOHAEMAGGLUTINATION AND RAYNAUD'S PHENOMENON

BY

G B FORBES, MB, ChB

Late Major R A M C Specialist in Pathology

Autohaemagglutination has been defined by Boxwell and Bigger (1931) as "a clumping of the erythrocytes into irregular masses, visible to the naked eye, occurring in the presence of the individual's own serum, without bacterial action, at air temperature and reversible at body temperature." The phenomenon has been fully studied by these authors and by Landsteiner (1903), Clough and Richter (1918), Yorke (1911), and others both in animals and in human subjects. As a result of their investigations a number of criteria have been established, these may be briefly summarized: (1) Autohaemagglutinins in the serum of an "auto-agglutinator" will produce agglutination of his own corpuscles at temperatures below that of the body. They are most active at 0° C, less active at room temperature, and inert at blood heat. (2) Autohaemagglutinins are capable of agglutinating, at low temperatures, not only autologous corpuscles but also those of other individuals irrespective of their blood group, and in some cases the corpuscles of various animals as well. (3) The reaction is reversible. Corpuscles which have been agglutinated at low temperatures will disperse on heating to body temperature and reagglutinate on cooling.

Because of their activity at low temperatures autoagglutinins are often referred to as "cold" agglutinins. The terms are not strictly synonymous. Broadly speaking, however, an auto-agglutinin may be regarded as non-specific "cold" agglutinin of such potency that it is active at room temperature. The difference then is largely one of "titre" and thermal range. The phenomenon is quite distinct from pseudo-agglutination which is due to excessive rouleaux formation, bacteriogenic haemagglutination which may occur when sera or cell suspensions are contaminated with certain organisms of the diphtheroid group (Thomson phenomenon), and from polyagglutinability, in which phenomenon the individual's corpuscles are agglutinated at low temperatures by most normal sera irrespective of their group agglutinins, but not by autologous serum (Gaffney and Sachs, 1943).

The sera of normal healthy individuals frequently contain small amounts of cold agglutinins which will produce weak macroscopic agglutination when the serum is mixed with corpuscles of the same group (or group O) at refrigeration temperature (0-7° C). The reaction is seldom demonstrable on dilution of the serum beyond 1/16 (Turner and Jackson 1943). Rarely a serum will stand considerable dilution (1/32, 1/64), and in very exceptional cases the agglutinin will be present in such strength as to produce obvious naked-eye agglutination at room temperature—that is auto-agglutination.

Of 10,000 sera from presumably healthy individuals 0.29% were found by Shooter (1943) to contain cold agglutinins active at room temperature. Errors in blood group determination are occasionally caused by the presence in an individual's serum or plasma of such an agglutinin. The small amount of plasma that is present in a citrate or saline suspension of the individual's corpuscles may be sufficient even on further dilution with grouping sera, to cause marked clumping of his own corpuscles, and a false diagnosis of group AB may be made. This source of error can be eliminated by carrying out the grouping test at 37° C, at which temperature

auto-agglutinins, but not the ordinary iso-agglutinins, anti-A and anti-B, are inactive

Autohaemagglutination occurs rarely and inconstantly in a variety of pathological conditions which have little or no nosological affinity. Boxwell and Bigger could find in the literature only 22 cases which they considered to be undoubted examples of the phenomenon. Of these, five were normal subjects and the remainder suffered from such diseases as severe anaemia, cirrhosis of the liver, syphilis, and leukaemia. Cold and auto-agglutinins, however, are found with some degree of regularity in the sera of patients with primary atypical pneumonia (Peterson *et al.*, 1943, Turner *et al.*, 1943), tropical eosinophilia (Viswanathan and Natarajan, 1945), and trypanosomiasis (Yorke, 1911), and their demonstration has been used as a laboratory aid to the diagnosis of these conditions.

Table Showing Cases of Autohaemagglutination with Peripheral Vascular Manifestations

No	Author	Case Notes
1	Iwai and Mei Sai (1925)	Male 36 Raynaud's phenomenon (R.P.)
2	Alexander and Thompson (1925)	Male 48 R.P. atypical leukaemia haemoglobinuria WR negative
3	Iwai and Mei Sai (1926)	Female 78 R.P.
4	Stieffel (1928)	Male 60 R.P. haemoglobinuria hepatomegaly
5	Davidson (1932)	Male 60 macrocytic anaemia suffered from cold hands
6	LeGoff (1933)	Male 67 R.P. chilblains
7	Roth (1935)	Male 59 R.P. haemoglobinuria
8	Salén (1935)	Male 50 acrocyanosis haemoglobinuria
9	Ernstene and Gardner (1935)	Male 38 R.P. haemoglobinuria
10	Szary Kipfer and Gharib (1938)	Male 60 R.P. haemolytic anaemia arteriosclerosis splenomegaly and hepatomegaly
11	Hanns and Sommer (1938)	Male 32 R.P. anaemia splenomegaly
12	Gautier Heimann and Laudat (1939)	Female 52 R.P. anaemia
13	Benians and Feasby (1941)	Female 65 R.P. anaemia
14	Davidsohn (1942)	Female 63 R.P.
15	Stats and Bullova (1943)	Male 64 R.P. dry gangrene of digits
16	Helwig and Freis (1943)	Male 38 acrocyanosis primary atypical pneumonia
17	McCombs and McElroy (1937)	Male 57 R.P. haemoglobinuria arteriosclerosis

The association of autohaemagglutination with symptoms of a peripheral vascular nature has been observed on several occasions. Iwai and Mei-Sai (1925, 1926) reported two cases of Raynaud's phenomenon with associated high-titre auto agglutinins, and were of the opinion that the peripheral vascular manifestations in their cases resulted from intravascular haemagglutination when the extremities were subjected to low environmental temperatures.

In 1937 McCombs and McElroy reviewed the literature on autohaemagglutination with special reference to its association with Raynaud's phenomenon. They were able to collect five case reports of this association, and they themselves added one more to the list. According to Stats and Bullova (1943), 14 accounts of this combination of phenomena had appeared in the literature by 1943. To these I would add four other case reports. They are by LeGoff (1933), Ernstene and Gardner (1935), Davidsohn (1942), and Helwig and Freis (1943).

Laboratory findings are given pride of place in most of the accounts in the literature and full clinical details are not always available. Intermittent pallor or cyanosis of the extremities, precipitated by exposure to cold, is the predominant clinical feature, and the demonstration of high titre cold or auto agglutinins in the blood is a constant laboratory finding. Attendant clinical features such as anaemia, haemoglobinuria, hepatic dysfunction, and organic occlusive disease of the peripheral vessels are found in the case reports. Males are affected more often than females and there is wide variation in age incidence. Few, if any, of the patients appear to have been suffering

from the true clinical entity called Raynaud's disease (see Table). The following account of a case which I investigated recently is submitted as an illustrative example of the association of autohaemagglutination and Raynaud's phenomenon.

Case Report

A 24-year-old American sergeant was admitted to hospital with the complaint that his fingers became blue and numb on exposure to cold environmental conditions. He had had several attacks in the course of a few days before admission, during which time the weather was moderately cold. An attack would develop if his hands were uncovered while out of doors or in bed at night. Each attack would last for 10 to 20 minutes and would be rapidly relieved by warmth. He stated that changes first appeared at the tips of his fingers. As a rule the tip of one finger of either hand would first become involved and the change would gradually extend to all the fingers of one or both hands. The palms and the dorsa of the hands were affected to a less degree than the fingers, the wrists and forearms were unaffected. Colour changes during an attack were rather variable and depended to a certain extent on whether he was in the upright or the recumbent position, and whether or not he took immediate steps to alleviate the condition. From his description it seems that the fingers assumed a mottled dusky tint with white and purple patches and areas of normal colouring. In one attack the white patches would predominate, in another the purple. During the recovery phase the fingers would become first pale orange in colour, gradually intensifying to red and then fading to the normal skin colouring. He stated that his fingers felt numb during an attack and that they "throbbed" for a short time afterwards. Occasionally the tip of his nose and the lobes of his ears would become blue. His toes and feet were not affected at any time.

His past history was essentially negative. Despite the fact that he had lived for many years in a very cold part of the United States he had not previously suffered from this complaint. He acted as a volunteer blood donor a few months before admission and at that time no abnormality was found on blood examination. There was nothing in the past history to suggest that he had suffered from trypanosomiasis. Mastoidectomy had been performed at the age of 6 years. Eight months before admission a small tumour situated at the right angle of the jaw had been removed. The patient (a highly intelligent man) stated that microscopical examination of the tumour revealed "inflammatory change only."

A few slightly enlarged lymph nodes in both axillae and in the left supraclavicular fossa were the only abnormal findings on physical examination. There was no wasting of the small muscles of the hands or clubbing of the fingers. Normal pulsation was felt in the main limb vessels. The skin over the extremities (when examined between attacks) appeared perfectly healthy and his hands felt quite warm. The spleen was not enlarged. Radiological examination of the chest revealed no abnormality.

During the patient's short stay in hospital the weather became much warmer and attacks did not develop spontaneously. However by immersing his hands in cold water it was possible to induce an attack. The colour changes already described were reproduced after a 15 minute immersion, with a rapid return to normal on placing his hands in warm water.

Laboratory Findings

That the patient was an "auto agglutinator" was first suspected when an attempt was made to do a blood count. Capillary blood issuing from a small puncture wound in the lobe of the ear was seen to agglutinate spontaneously and large clumps of corpuscles were present in the diluting pipette. Under these circumstances it was impossible to carry out an accurate blood count, but by warming the patient's ear with a hot-water bottle and using pipettes and diluting fluids which had been warmed to 37°C before use agglutination was temporarily prevented and a reasonably accurate blood count obtained. This count showed haemoglobin 98% (Haldane), red cells 4,900,000 per cmm, white cells 6,000 per cmm (neutrophil polymorphs 3180, lymphocytes 2,520, monocytes, 300), platelets, 370,000 per cmm. A film revealed nothing

abnormal. The patient's blood group was determined by carrying out the test at 37° C. He was found to belong to group B. The bleeding time and clotting time were normal. The erythrocyte sedimentation rate (Wintrobe) at 37° C was 1 mm in 1 hour (the true reading), at 22° C 47 mm in 1 hour—a false result owing to the rapid sedimentation of cell clumps, at 4° C large cell masses prevented sedimentation. The Kahn and Donath-Landsteiner reactions were negative, as was the Paul-Bunnell reaction when carried out at 37° C. The urine revealed nothing abnormal.

Venepuncture was next performed and the blood sample placed in both oxalate and plain containers. These were immediately transferred to the incubator; clot retraction was allowed to take place at 37° C and the following experiments were carried out, using the serum thus obtained.

1 One drop of the patient's serum was added to one drop of a 5% saline suspension of his own corpuscles on a porcelain tile at room temperature. Complete agglutination of the corpuscles occurred almost immediately. The porcelain tile with the serum corpuscle mixture still showing marked agglutination was then transferred to the incubator at 37° C. The tile was re-examined after 10 minutes at 37° C. Dispersion of the corpuscles had occurred so that a homogeneous suspension of corpuscles in serum resulted, and there was no trace of agglutination. Reagglutination of the corpuscles took place when the tile was left at bench temperature (22° C) for several minutes. Agglutination or deagglutination could be produced indefinitely by alternate cooling and warming of the serum corpuscle mixture.

2 The above experiment was repeated using several suspensions of group AB, A, B, and O corpuscles instead of autologous corpuscles. The same result was obtained with B and O suspensions. With AB and A suspensions agglutination persisted at 37° C because of the anti-A iso-agglutinin in the patient's serum.

3 A 1% saline suspension of washed autologous corpuscles was added to a series of dilution tubes containing progressive geometric dilutions of the patient's serum, so that the final dilutions of serum were 1/4 to 1/4096. The tubes were placed in the refrigerator at 4° C overnight. The following morning the corpuscles were resuspended in the supernatant fluid by rapidly inverting each tube three times and the highest dilution which showed naked-eye agglutination was taken as the end-point. A titre of 1/204 was thus obtained. The same titre was reached when the patient's serum was titrated against suspensions of O and B corpuscles. This titre remained constant throughout the patient's stay in hospital.

Comment

It has been shown experimentally that the abnormal agglutinin in this patient's serum was a true autohaemagglutinin. The disease or factor responsible for its presence was not, however, determined. The fact that no abnormality was detected on physical and radiological examinations of the chest does not altogether exclude the possibility that he had suffered recently from a subclinical attack of primary atypical pneumonia, a disease which was encountered not infrequently among Service personnel in North-West Europe at the time of his admission. It is known that primary atypical pneumonia may assume a very mild subclinical form, and Turner *et al.* (1943) record a case of the disease in an ambulant female patient, radiologically negative, whose serum contained cold agglutinins to a titre of 1,000 and whose only complaint was of a bad cough.

There can be little doubt that the peripheral vascular manifestations in the case presented were due to mechanical blockage of the small peripheral vessels by aggregations of corpuscles within their lumina, the activating factor being exposure to cold. Cold exerted its influence in a twofold manner: (a) by lowering the temperature of the exposed extremities to the critical level for auto-agglutination to occur, and (b) by producing simultaneously a constriction of these vessels—the normal response of peripheral vessels

to cold stimuli (Lewis, 1936). The lumina of the vessels were thus almost completely occluded and the clinical features of Raynaud's phenomenon produced. In true Raynaud's disease obliteration of the vessel lumen is brought about by intense spasm of the vessel. Although the mechanism of production of vascular obliteration is different in the two conditions the end-result is essentially the same (see diagram). The peripheral vascular manifesta-

Diagram showing the effect of exposure to cold on the lumen diameter of small arteries. A, in normal subjects; B, in true Raynaud's disease; C, in Raynaud's phenomenon due to autoagglutination.

tions readily disappeared when heat was applied to the affected extremities, owing presumably to dilatation of the peripheral vessels and dissolution of the corpuscle aggregations. A free flow of blood to the parts was thus re-established.

The patient informed me by letter three months after his discharge from hospital that he was then symptom free and that a blood examination for cold and autoagglutinins was negative.

Summary

The literature on autohaemagglutination, with particular reference to its association with symptoms of a peripheral vascular nature, has been reviewed. Some 18 cases of this combination of phenomena are on record.

A case of autohaemagglutination with peripheral vascular crises has been described. It is suggested that the Raynaud-like attacks which followed exposure of the patient's extremities to low temperatures resulted from blockage of the small peripheral vessels with corpuscular aggregations. The results of *in vitro* experiments on the blood lend support to this contention and are probably a true reflection of the changes which occurred *in vivo*.

The aetiological factor responsible for the presence of the abnormal agglutinin was not determined.

Medical Memoranda

A Case of Periarteritis Nodosa

Periarteritis nodosa is a rare and generally fatal disease. Perilman (1946) thinks that every case deserves special attention therefore I record the following case.

CASE REPORT

An Army driver aged 31 was taken ill with malaise, aches and pains, especially in the left side of the chest, and cough while in Greece. He was admitted to 53 General Hospital on April 24, 1946. On examination no abnormal physical signs were found, although a skiagram of the chest taken two days later showed a mild opacity in the left mid zone suggestive of resolving pneumonia. Atypical pneumonia was suspected. He soon ceased to complain of any specific symptoms, but his temperature remained raised. On April 30 the white cell count was 13,800 per cmm (polymorphonuclear neutrophils, 73%, lymphocytes, 20%, eosinophils, 4%, monocytes, 2%, basophils, 1%). On May 3 radiological examination of the chest was normal and the urine showed only a few pus cells. Throughout his prolonged stay he had pyrexia, usually 101-101.5 F (38.3-38.6°C) but occasionally as high as 103 F (39.4°C). All pathological investigations were negative. Three blood cultures were sterile and repeated stool examinations were negative for amoebae or cysts and pathogenic organisms. Agglutination tests for enteric fevers and brucellosis were negative on May 10, May 27, and June 22. At times he complained of abdominal pains, and on May 24 he had pain in the left foot. On June 22 his spleen was palpable. On June 29, 30,000 units of penicillin was injected three hourly, 2,000,000 units being given without effect.

He was transferred to 72B General Hospital on July 10 as a possible case of undulant fever. Here no abnormal physical signs were found except slightly enlarged lymph glands in the neck and axillae, and one was removed for biopsy. His temperature was still raised and his white cell count was 11,800 per cmm, 7% being eosinophils. Undulant fever was suspected but not confirmed.

He was returned to England and admitted to Q A Military Hospital, Horley, on Aug 9. His liver and spleen were enlarged and tender, a few shotty glands were palpable, the left ankle jerk was absent, and there was numbness in the left leg. A blood count showed red cells 4,160,000 per cmm, Hb, 78%, colour index, 1.9%, white cells, 14,200 per cmm (polymorphonuclear neutrophils 70%, lymphocytes, 17%, eosinophils 3%, monocytes 2.5%, basophils, 0.5%). A midstream specimen of urine showed an occasional granular cast, scanty pus cells, and a scanty growth of *Staph. albus* (? contaminant). Blood culture was sterile. Serum agglutination tests for brucellosis and enteric fevers were negative. A skiagram of the chest was normal and the Wassermann reaction and Kahn test were negative. On Aug 16 a neurologist reported: 'I think that this man's neurological signs in the left leg are indicative of a lateral popliteal nerve lesion. In view of the aching pain in both calves for two weeks before the numbness came on in the left leg I think the cause is probably a toxic neuritis'. About this time there was pronounced abdominal pain but a plain skiagram showed nothing abnormal and radiological examination of the spine was also negative.

On Aug 22 the biopsy report was: 'The picture is that of a malignant reticulosis, probably an early example of Hodgkin's disease'. The slides were considered to be 'strongly suggestive of lymphosarcoma'. On Sept 5 the patient was seen at the Middlesex Hospital with a view to treatment by deep x ray therapy. At this hospital the histological report was: 'Section shows areas of proliferation of endothelial cells, but the gland structure is preserved and there is no definite evidence of Hodgkin's disease'.

On Sept 17 the patient was admitted into Mount Vernon Hospital under my care. He was very ill and emaciated, and complained of abdominal pain and severe nausea. A few small glands were palpable in the neck and axillae. The liver was enlarged but the spleen could not be felt. Temperature 100 F (37.8°C). Shortly after admission he went into status epilepticus obviously due to intracerebral involvement. He died on Sept 24, five months from the onset of the illness.

Post mortem Examination—(1) Small nodules were present along the coronary arteries. (2) The brain showed general congestion and a small cerebral haemorrhage involving the cortex of the left lateral aspect of the occipital lobe. (3) The liver was enlarged, pale and mottled, showing marked toxic changes and several infarcts. (4) Both kidneys were swollen and mottled, and showed severe toxic changes and numerous small infarcts. (5) The spleen was enlarged but contained an infarct. (6) The small and large intestines were distended and flecked with small fibrino purulent

deposits. Many adhesions were present between various coils. The small intestine at the adherent areas showed thickening, the mucosa being covered by a rough exudate spreading circularly round the lumen, no definite ulcers were seen. The arteries supplying these areas showed some thickening but no definite nodules. The caecum contained areas of mucosal ulceration—probably a post-mortem change. (7) There were a few slightly enlarged glands in the neck and axillae.

Histological Examination—Heart: one section showed a typical mycotic aneurysm, and the others occlusive fibrotic changes in the vessels. Brain: section revealed haemorrhage, but destruction too extensive to show typical vessel changes. Liver: a large infarcted area with inflammatory infiltration and sprouting bile-ducts surrounding it, no typical vessel changes. Kidney: a small infarct and a vessel at the edge of it completely occluded by fibrous tissue. Spleen: an infarct present, some of the small vessels showed thickening but no aneurysm or complete occlusion was seen. Mesenteric vessels: occlusive changes. Gland: congested, there was retention of normal architecture, hyperplastic changes only.

Death was thus due to periarteritis nodosa the most typical lesions being in the coronary arteries.

DISCUSSION

This disease most commonly affects young adults. The principal vessels involved are those of the heart, intestine, and kidney, but the vessels of the brain, lungs, and limbs may be more rarely involved. There are fever, prostration, and loss of weight, and a remarkably varied symptomatology, as vascular involvement may occur in almost any organ. The abdominal symptoms in the above case were due to occlusion of the mesenteric vessels, while the neuritic pains were probably the result of occlusion of the nutrient arteries to the peripheral nerves. The immediate cause of death was involvement of the cerebral arteries.

The diagnosis is usually made post mortem. Occasionally, however, when nodules are present in the subcutaneous tissue biopsy will give a correct diagnosis. In the above case various diagnoses were suspected at the beginning: atypical pneumonia, and later undulant fever, toxic neuritis, and reticulosis. In Perilman's (1946) case infective polyneuritis was first suspected and later abdominal Hodgkin's disease. The condition may be due to a filtrable virus, but there is much evidence to suggest that it is a form of vascular hypersensitivity. Thus the disease may occur in patients who have suffered from asthma, serum sickness, or sulphonamide reaction. Miller and Nelson (1945) described a case occurring during antisyphilitic treatment, and suggested that the condition represents in this case an anaphylactic type of hypersensitive response to arsenicals. Again, Rich and Gregory (1943) have produced characteristic lesions in rabbits by repeated injection of horse serum. Eosinophilia, usually moderate, may be found in some cases, and also supports an allergic aetiology. Friedberg and Gross (1934) consider that some cases may be rheumatic in origin.

The disease is commonly fatal, death often being due, as in this case, to haemorrhage from a ruptured aneurysm. In some cases, however, though the condition may continue for months recovery may occur, but in some of these late symptoms of renal and cardiac insufficiency may develop, as in the case described by Arkin (1930). Treatment is in the main symptomatic and supportive but every effort should be made to exclude antigens that might be responsible.

I wish to thank Dr Ruth Pearson for the post mortem examination.

INFECTIOUS DISEASES

The Background of Infectious Diseases in Man By I. M. Burnet, M.D. F.R.S. (Pp 110 7s 6d) Melbourne The Melbourne Permanent Postgraduate Committee, College of Surgeons, Spring Street

The present volume is a reprint of six postgraduate lectures delivered in 1945 at Melbourne. The author treats infectious disease from the oecological standpoint, illuminating particular aspects with broad generalizations and with recent scientific knowledge. Besides being useful to general practitioners, for whom they were originally intended these lectures should have a salutary effect on specialists, particularly those whose conceptions have become fixed or their vision narrowed.

An introductory lecture is followed by one on diphtheria, measles, rubella, and infectious jaundice. The author is exasperated by the fact that all the common infectious diseases having a long incubation period, such as chicken pox, measles, rubella and mumps, are caused by viruses that cannot be studied adequately in the laboratory. At most they cause a very mild illness in monkeys. He thinks, however, that the outburst of symptoms and rash in the exanthemata is due to a relatively massive liberation of virus into the blood, and such an intense antibody response then occurs that subsequent immunity is life long. In the third lecture he suggests that infectious disease must have evolved almost entirely among gregarious animals and that poliomyelitis, for example, may have been introduced into the human species from an animal such as the mouse, which suffers from a similar disease. The older age incidence of poliomyelitis that has been noted in some countries recently may be a result of their people's higher standard of living which has protected the infants and young children from exposure to infection. In the fourth lecture, on streptococcal infection and rheumatic fever, he points out that hypersensitivity to bacterial products requires the prolonged production of bacterial antigens in the immediate neighbourhood of an accumulation of monocytic inflammatory cells. He regards it as probable that antigen lodging in situations of choice, such as the joints reacts with antibody when the latter reaches a certain level in the blood, rather than that tissues sensitized by previously formed antibody respond to antigen set free from the local site of infection. He considers that the common febrile infections of the respiratory tract with the exception of those due to haemolytic streptococci are primarily caused by viruses. Discussing the possibility of successful vaccination against influenza he draws attention to the fact that herd immunity lasts longer than individual immunity probably because a lower general level of immunity is necessary to prevent the spread of infection through the herd than to protect the individual against concentrated exposure. In the last lecture on tuberculosis, he emphasizes that to prevent this disease the one outstanding requirement is to protect against primary infection with the tubercle bacillus. He dismisses the fear that the virtual abolition of tuberculosis from a community would result in the development of a highly susceptible population since most of the extremely susceptible combinations have been eliminated from the race in the past 200 years and it would take a long time for serious changes to occur in the current distribution of genetic resistance.

LECTURES FROM EDINBURGH

Edinburgh Postgraduate Lectures in Medicine Volume 3 (Pp 588 illustrated 15s) Published for the Honyman Gillespie Trust by Oliver and Boyd, Edinburgh 1946

This volume which exemplifies the high level of didactic teaching characteristic of the Scottish schools of medicine comprises lectures by thirty-two different lecturers—all from Scotland and most from Edinburgh itself—delivered and published under a grant received by the executive committee of the Edinburgh postgraduate courses from the trustees of the late Mrs Honyman Gillespie. Nevertheless it has proved more difficult to read than any recently received volume. In reviewing some French lectures on clinical medicine a short time

ago we asked whether the dry of the published clinical lecture had not passed, the question is even more apposite when the lectures are given by over thirty different authors and, owing to the fortunes of war, are not published until three or four years after delivery.

It is difficult for any one reader to be interested both in the Control of Sepsis and in Delinquency, in the First Month of Life and in Prostatic Enlargement. Such diverse material is more suited to the special journals, where the reader's appetite is stimulated by the limited size and the sense of news, and to be blunt, it seems a waste of time and money to publish such material in a beautifully bound and printed volume of nearly six hundred pages. To-day is the day of the monograph and the symposium. How valuable, for example, would be a symposium on all that has been learned and recalled about malnutrition in the past eight years. It may well be that the committee which nominates and invites the lecturers should adopt a different policy in postgraduate education and publication. Only pious devotion to an *alma mater* would justify the purchase of these addresses, and it is certain that the collective genius of the Edinburgh school could pay some more fitting tribute to the memory of Mrs Honyman Gillespie.

L. J. WITTS

AESTHETIC LAPAROTOMY

Laparotomia Estetica en la Mujer By Dr Carlos Lorea (Pp 66 No price given) Madrid Editorial Científico Médica 1946

In this well illustrated monograph the author pleads for greater care in the planning of laparotomy incisions in gynaecological operations, and stresses the mental trauma inflicted on women condemned to bear unsightly operation scars on their abdomens. He makes a transverse incision with the convexity downwards not exceeding 10 cm in length, and with its centre about 4 cm above the symphysis pubis, so placed and of such size that the pubic hair will hide the scar. It is traced accurately by applying to the abdomen a sterile plate of thin steel which is fitted with a hook that rests against the pubis, a linear perforation marks the line of the proposed incision, and the suture lines are also delineated exactly and symmetrically. Methylene blue solution can be used to trace the line if iodine is employed as the skin disinfectant.

The skin and aponeurosis are incised along the line, and the lower flap of the aponeurosis is divided longitudinally in the midline to gain space, and then dissected off the underlying muscle. The recti are separated, and the peritoneum is incised longitudinally a self-retaining retractor is inserted. The exposure obtained is sufficient to perform conservative operations on uterus and adnexa, appendicectomy, or even a lower segment caesarean section. The wound is closed in four planes. The peritoneal edges are approximated with a continuous chromic catgut stitch, the recti with three mattress sutures, and the edges of the aponeurosis first with several interrupted catgut sutures and then with a continuous stitch. The skin is sutured with a few mattress stitches of silk worm gut, taking in the subcutaneous fat, and is finally closed with Michel clips. The photographs of cases in which this technique has been used seem to justify aesthetically the author's claims for his incision.

S. S. B. GILDER

CARDIOLOGY

Diseases of the Heart and Circulation By Albert A. Fitzgerald Peel, D.M., F.R.F.P.S. Oxford Medical Publications (Pp 393, 61 illustrations 35s) London and New York Geoffrey Cumberlege (Oxford University Press) 1947

This book is dated 1947, the author's preface September, 1946 and the student and practitioner for whom the book was primarily written would therefore expect to find in its pages the most recent information on the cardiovascular system and the treatment of its ailments. They will be disappointed. The most important new facts have been discovered by means of multiple chest lead electrocardiography, vectorcardiography, phonocardiography, angiocardiology, measurement of peripheral blood flow and especially cardiac catheterization. Yet the author mentions neither these methods nor the facts revealed by them. The most important new therapeutic agents in cardiology include penicillin, thiouracil, heparin, dicoumarol

thecophylline ethylene diamine cholinergic substances magnesium sulphate and lumbo dorsal sympathectomy, little or nothing is said about any of them.

The author rightly stresses the importance of functional as well as structural changes, but it can hardly be said that he has achieved his purpose 'to present the morbid physiology of the circulation side by side with its morbid anatomy'. He omits to discuss the hyperkinetic circulatory state associated with thyrotoxicosis, anaemia severe emphysema, arteriovenous aneurysm, beriberi, and extensive Paget's disease. Cardiac asthma is identified with the dyspnoeic phase of Cheyne Stokes breathing when complicated by bronchial spasm (p. 19), effort dyspnoea and cyanosis in patients with diminished cardiac reserve or with pulmonary congestion are attributed to excess of carbon dioxide (p. 5) and to deficient oxygenation of the blood (p. 20) respectively, palpitation and left inframammary pain to lowering of the sensory threshold to normal afferent impulses (p. 14) and jugular pulsation to tricuspid incompetence (pp. 21 and 202). The description of triple rhythm is especially confusing (pp. 37-40).

On the whole the author's views on morbid anatomy are orthodox, but the statement that syphilis is a cause of aortic stenosis (pp. 193 and 221) will not find many supporters, nor will the belief that adherent pericardium is a cause of great cardiac enlargement and that it should be treated by the operation of cardiolysis (p. 175). Recommendations for treatment are thoroughly conservative, even to the point of denying the value of quinidine in paroxysmal tachycardia (p. 113). The merits of the book are simplicity, economy of words, clarity of expression, lack of repetition, plentiful electrocardiographic and radiological illustrations, and a sensible division of the book into three main sections: (1) symptoms and signs, (2) anatomical lesions, (3) retiological types of heart disease. The bibliography is deliberately scanty and predominantly British.

PAUL WOOD

HOSPITAL STATISTICS

The Hospitals Year Book 1945-6 Edited by J. P. Wetenhall, B.A. (Pp. 279, 21s.) London: The British Hospitals Association, 1946.

In this edition of the *Hospitals Year Book* which appeared at the end of 1946, the latest statistics are those for 1942, for the figures concerning the finance and work of the voluntary hospitals are compiled from annual reports issued in the year after the one to which they relate. This year difficulties have further delayed publication. The statistical analyses are interesting for historical record. In 1942 subscriptions and donations accounted for 18% of the income of voluntary hospitals, legacies for 8.4%, patients' contributions for 41.6%, and receipts for public services for 21.7%. The hospitals were solvent, maintenance income exceeding expenditure by nearly 2.1 million pounds.

The *Hospital Directory* is the more useful part of the volume and presents much information compactly. The number of available beds at each voluntary hospital is given, together with the pre-war number. Of the twelve hospitals with medical schools ten have fewer beds available and only two (Kings College and University College) rather more but in the provinces and Scotland the trend is, in general, the other way. Particulars of accommodation for private patients and the fees charged, of the employment of almoners, dietitians, and others, of reservation of beds, and of approval for nursing training and other purposes are all given. A list of municipal and public assistance hospitals, of convalescent homes, and of contributory and provident schemes is included, and the result of an inquiry into an appointment system for out-patients with a suggested method of operating such a system, is an interesting feature.

Rehabilitation varies from a slap on the back and 'Well I don't want to see you again my lad!' to an educative process lasting many months—beginning perhaps with quadriceps exercises in bed and ending with a bicycle ride. In *The Road Back to Health* (H.M.S.O. price 6d.) which briefly describes and illustrates much of the apparatus of rehabilitation Mr. Aneurin Bevan gave in a foreword. This is a field in which Britain leads the world. This pamphlet is intended to appeal to laymen as well as doctors.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Sensory Mechanisms of the Retina By Ragnar Granit, M.D. (Pp. 412, 35s.) Oxford University Press. Geoffrey Cumberlege, 1947.

An account of investigations into the electrical signs of excitation and inhibition in the retina and optic nerve, the properties of rods and cones, photosensitive substances and the mechanism of excitation, and colour reception by the professor of neurophysiology at the Royal Caroline Institute, Stockholm.

Transactions of the Third Tuberculosis Workers' Conference Held in New Delhi (Pp. 188, Rs. 4.) New Delhi: Tuberculosis Association of India, 1947.

Addresses on various aspects of tuberculosis delivered in New Delhi in 1945.

A Handbook of Midwifery By Sir Comyns Berkeley, F.R.C.P., F.R.C.S., F.R.C.O.G. 13th ed. (Pp. 456, 12s. 6d.) London: Cassell, 1946.

This textbook for pupil midwives, midwives and obstetric dressers contains new material on the rhesus factor, and sections on the treatment of unavoidable haemorrhage and blood transfusion have been rewritten.

Actions and Uses of Drugs By Windsor C. Cutting, M.D. (Pp. 326, 16s. 6d.) California: Stanford University Press, 1946.

A summary of the effects and uses of drugs intended as a textbook for nurses, includes sections on antibiotics, hormones, and vitamins.

Womanhood By Margaret M. White, M.D., F.R.C.S., M.R.C.O.G. (Pp. 107, 7s. 6d.) London: Cassell, 1947.

The purpose of this book is to help women to understand the anatomy and physiology of their sexual and procreative functions, written from a practical point of view and illustrated with diagrams.

Tension Arterial y Biotipo By Fidel Schaposnik. (Pp. 121, No price.) Buenos Aires: Librería y Editorial "El Ateneo", 1947.

A monograph on blood pressure with biological evidence. In Spanish.

Gestation Periods Technical Communication No. 5. Compiled by J. H. Kenneth, M.A., Ph.D., F.R.S.E. 2nd ed. (Pp. 30, 3s.) Edinburgh: Imperial Bureau of Animal Breeding and Genetics, 1947.

A table on the gestation periods of many animals, with bibliography.

Nuove Vedute sulla Malaria By Maurizio Ascoli et al. (Pp. 209, No price.) Rome: Istituto Bibliografico Italiano, 1947.

A collection of papers on malaria by Italian authors.

Pediatric Gynecology By Goodrich C. Schauffer, A.B., M.D. 2nd ed. (Pp. 380, \$6.00.) Chicago: Year Book Publishers, 1947.

Many sections in this book have been revised, including those on gynaecological surgery, medico-legal aspects, and commercial preparations of sex hormones.

My Eyes Have a Cold Nose By Hector Chevigny. (Pp. 253, 12s. 6d.) London: Michael Joseph, 1947.

An account by a blind man of his reactions to blindness and of the dogs trained to guide the blind.

Micro-diffusion Analysis and Volumetric Error By Edward J. Conway, M.B., D.Sc. (Pp. 357, 21s.) London: Crosby Lockwood, 1947.

Includes an account of new methods of micro-diffusion technique. Part I describes apparatus and principles used in micro-diffusion analysis. Part II methods with the standard "unit," and Part III the error of volumetric titration.

Uterotubal Insufflation By I. C. Rubin, M.D., F.A.C.S. (Pp. 453, 50s.) London: Henry Kimpton, 1947.

A clinical account of tubal insufflation and an evaluation of the aetiological importance of obstructed uterine tubes in sterile matings, with description of the anatomy, physiology, and pathology of the Fallopian tubes.

Penicillin in General Practice By J. L. Hamilton Paterson, M.D. 2nd ed. (Pp. 110, 5s.) London: Staples Press, 1947.

An account of the administration and uses of penicillin in general practice with a section on the nature and properties of penicillin.

FOLIC ACID

It is now eighteen months since Spies¹ and his co-workers in America first reported the haemopoietic properties of folic acid in man. This recently synthesized member of the vitamin B complex has been recognized as an essential food factor for many years. Under the names vitamin B₁₂, eluate factor, *Lactobacillus casei* factor, *Streptococcus lactis* R factor, and vitamin M, crude preparations of folic acid have been shown to have a haemopoietic function in a number of species. A deficiency profoundly depresses the formation of red and white cells and platelets. With the synthesis of folic acid in 1945 by Agnier and his team² the pure substance has become available in quantities adequate for clinical trials. The results of many of these have been published, and it is now possible to review the therapeutic uses and limitations of folic acid and to speculate on its mode of action. Sufficient evidence has accumulated to prove that synthetic folic acid produces a haemopoietic response similar to that resulting from adequate liver therapy in many types of megaloblastic anaemia, including Addisonian pernicious anaemia, and the anaemias associated with sprue, pellagra, pregnancy, infancy, and malnutrition. It is ineffective, however, in the treatment of anaemias due to iron deficiency, the leukaemias, and the anaemias associated with hypoplasia or aplasia of the bone marrow. It appears to be effective only in cases of anaemia with a megaloblastic bone marrow. Leucopenia and thrombocytopenia have been produced in animals fed on purified diets deficient in folic acid, but it has proved successful in treating patients suffering from these conditions only when they have formed part of a syndrome resulting from a nutritional deficiency. Although it is the opinion of most workers that folic acid is ineffective in the treatment of aplastic anaemia, Gendel³ states that he has produced improvement in three patients with massive doses of 150 to 400 mg of folic acid daily (normal dose 5 mg to 10 mg daily). It may well be that the improvement observed was a coincidental spontaneous remission, but as a progressive marrow hypoplasia and aplasia can be produced in rats by feeding diets deficient in folic acid⁴ Gendel's massive dose therapy might repay further investigation.

The evidence for the value of folic acid in relieving the anaemia of sprue is conflicting. Spies and his colleagues⁵ have reported not only a striking haematological response, but also the disappearance of the oral and gastro-intestinal symptoms and a gain in weight in cases of tropical sprue in Cuba. A remarkable improvement in the radiological appearances of the gastro-intestinal tract was also described,

including the disappearance of mucosal oedema and intestinal segmentation, spasm, dilatation, and hypomotility. Davidson and his co-workers⁶ in Edinburgh have confirmed the dramatic control of the diarrhoea and the rapid clinical improvement in cases of tropical sprue and idiopathic stercorrhoea, but they consider the haematological response very disappointing. They emphasize a clinical finding that has not been reported before—namely, a considerable improvement in intestinal function on the fifth day of treatment with folic acid, before the appearance of any blood changes. This dramatic change, which may occur in patients who show no haematological response to continued folic acid therapy, suggests that folic acid may have two distinct actions—the continuation of normoblastic blood formation, and the control of normal functioning of the alimentary system. Davidson observed no beneficial effects from giving folic acid to patients with coeliac disease or idiopathic ulcerative colitis. It is possible, as he points out, that the excellent haematological response seen by Spies in his sprue patients treated with folic acid may have been due to the fact that they had subsisted on deficient diets for long periods, and that many of them had infections and infestations of the gastro-intestinal tract. They were therefore probably suffering from both a direct and a conditioned nutritional deficiency, whereas in the Edinburgh series the deficiency was conditioned by a failure in absorption or utilization. Davidson is inclined to believe that the Cuban cases were mainly patients with primary nutritional macrocytic anaemia suffering from gastro-intestinal symptoms. This would certainly explain the difference in the response of the two series.

One thing is certain. Folic acid is not identical, either chemically or therapeutically, with the anti-pernicious anaemia principle of liver. Efforts to demonstrate significant amounts of folic acid in liver fractions have failed, and attempts to liberate free folic acid from ground muscle treated with gastric juice, according to the technique of Castle, have also been unsuccessful.^{7,8} It has been estimated that an effective dose of liver contains less than 1 mg of folic acid, a quantity which is unlikely to produce a haemopoietic response itself. The active principle of liver is evidently not folic acid but a totally different compound, which, if ever isolated, will probably be many times more potent than folic acid. Clinically there are important differences between liver extracts or proteolysed liver and folic acid. Certain anaemias of indefinite origin respond to liver extracts but not to folic acid, which appears to be effective only in cases with a megaloblastic bone marrow, some cases of megaloblastic anaemia are refractory to potent purified liver extracts but respond to folic acid, and, what is very important clinically, the neurological sequelae of pernicious anaemia can be both controlled and prevented by liver extracts but not by folic acid. Spies and Stone⁹ have recently shown that folic acid has no effect on the subacute combined degeneration of the spinal cord associated with this disease. Not only did folic acid fail to relieve the symptoms in their patients but the neurological lesions progressed while folic acid was

¹ *Sth. med. J.* 1945 38 707² *Science* 1945 102 227³ *J. Lab. clin. Med.* 1947 32 139⁴ *Arch. Path.* 1945 40 364⁵ *J. Amer. med. Ass.* 1946 132, 906 *Amer. J. Roentgen* 1946 56 337*J. Lab. clin. Med.* 1946, 31, 227⁶ *Lancet* 1947 1 511⁷ *Amer. J. med. Sci.* 1945 209 520 *Proc. Soc. exp. Biol. N.Y.* 1946 62 112⁸ *Proc. Soc. exp. Biol. N.Y.* 1946 63 555⁹ *Lancet* 1947 1 174

being administered. This report has now been confirmed by Davidson and Girdwood in a contribution in this issue of the *Journal* and by several American workers.¹⁰ It would appear that in liver there is an unknown factor or factors other than folic acid essential for maintaining the integrity of the nervous system in patients with pernicious anaemia. This failure to control the neurological complications of pernicious anaemia constitutes a serious limitation to the use of folic acid in the treatment of this disease. It can be recommended only as a temporary measure in the initial stages of treatment and in patients sensitive to liver undergoing desensitization, parenteral liver therapy must still remain the treatment of choice. Since neurological changes rarely develop in nutritional megaloblastic anaemia, pernicious anaemia of pregnancy, refractory megaloblastic anaemia, and the sprue syndrome, folic acid can be safely administered both for the initial and maintenance therapy of these conditions in doses of 5 mg to 10 mg daily. Treatment of any megaloblastic anaemia with doses of more than 10 mg daily is wasteful and unnecessary. At present prices folic acid is so much more expensive than liver extracts that it is not likely to replace liver therapy in treatment. According to Spies¹¹ a further drawback to the use of folic acid is that for constancy and speed of haemopoiesis it is inferior to a potent liver extract.

How does folic acid function in cases of megaloblastic anaemia? It is not the maturation factor for primitive red cells itself, because if it is incubated, either alone or in the form of its conjugate, with centrifuged marrow cells it fails to bring about maturation of red cells from their primitive precursors to the mature reticulocyte stage. In similar circumstances liver extract does.⁸ Folic acid is widely distributed in foodstuffs, and the possibility of a deficiency in the diet is extremely unlikely in this country, although it may occur in the patient suffering from malnutrition. Folic acid does not occur free in foods but as a conjugate with hexaglutamic acid, known as pteroylhexaglutamylglutamic acid, which is normally broken down in the body. There is now sufficient evidence to show that free folic acid is an essential factor for the continuation of normoblastic blood formation and that a deficiency causes a reversal to the megaloblastic condition. A deficiency of free folic acid may result from a diminished intake of the conjugate, as in nutritional macrocytic anaemia, failure to absorb the conjugate, as in the sprue syndrome, or failure to break down or utilize the conjugate, as may occur in pernicious anaemia. Welch¹² and Bethell¹³ have shown that folic acid conjugate will not produce a haemopoietic response in patients with pernicious anaemia who respond to free folic acid alone or to a hydrolysed conjugate. Such patients also fail to excrete significant amounts of folic acid in their urine after treatment with the conjugate, although they do so after the administration of free folic acid. It would thus seem that pernicious anaemia patients either do not absorb folic acid conjugate from their food or else they do not utilize it. When a potent liver extract is given parenterally to a pernicious anaemia patient there is a haemopoietic response and a

marked excretion of free folic acid. Evidently liver extracts contain a factor liberating free folic acid from its conjugate.

Pursuing this theme, Davidson and Girdwood assume that this liberating factor, a product derived from the interaction of Castle's intrinsic and extrinsic factors in the alimentary tract, is absorbed from the intestine and stored in the liver of normal subjects, but not in the liver of pernicious anaemia patients. The cause of pernicious anaemia is not primarily due to a defect in the bone marrow but to the inability of the patient to convert conjugated folic acid to the free form through lack of the liberating factor. Hence the administration of either free folic acid, or liver containing the liberating factor, ultimately provides the bone marrow with the folic acid necessary for normoblastic blood formation. In nutritional macrocytic anaemia, the sprue syndrome, pernicious anaemia of pregnancy, and idiopathic refractory megaloblastic anaemia, megaloblastic blood formation is not the result of defective production of the liberating factor postulated by Davidson and Girdwood but of a deficiency of folic acid conjugate resulting from insufficient intake or failure of absorption. In such cases it is understandable why therapy with purified liver extracts may fail and yet succeed with folic acid. This very plausible explanation of the mode of action of folic acid will need some modification in the light of the recent observation that it may be synthesized by the organisms in the human gut, since the combined faecal and urinary excretion is greater than the intake in the diet.¹⁴

ARTIFICIAL INSEMINATION

In all discussions of human artificial insemination a sharp line is necessarily drawn between insemination with the husband's semen and with that of some other man. The conference¹⁵ sponsored by the Public Morality Council in 1946 produced varying views on the moral, social, and other implications of artificial insemination by the husband (AIH), but all the lawyers who have dealt publicly with the subject agree that AIH raises no special legal questions. These only start to arise in relation to artificial insemination by a donor (AID). They are the more numerous and troublesome for the almost complete lack of authority, either in statute or in decision. The application of existing principles, however, does enable some answers to be given with reasonable confidence. There seems to be general agreement that a child produced by AID is illegitimate. For the truth of this statement lawyers cite Lord Dunedin's words in *Russell v Russell*¹⁶ "The appellant conceived and had a child without penetration having ever been effected by man, she was fecundated *ab extra*. The jury came to the conclusion that she had been fecundated *ab extra* by another man, unknown, and fecundation *ab extra* is, I doubt not, adultery." A Canadian court trying an AID case¹⁷ held that the introduction into a wife's body by unusual means of the seed

of a man other than her husband is adultery Mr H U Willink (recently Minister of Health), commenting on this decision,¹⁸ has observed that the adulterous character of an act cannot be removed by the consent of the other spouse, its consequences may be affected by connivance or condonation, but it remains an act of adultery. Similarly a donor commits adultery if his semen is used for AID.

Though aiding and abetting adultery is neither a criminal offence nor an actionable wrong and though it would strain legal imagination too far to suggest that a medical practitioner who practises AID is himself guilty of adultery, yet clearly he stands on insecure ground and close to a number of dangerous pitfalls. The first of these is the law governing the registration of births. The mother and her husband are in a dilemma. If he is registered as the father of the child they infringe the Perjury Act, 1911, and become liable to a fine of £50 on summary conviction or seven years' penal servitude if convicted on indictment. Mr Willink therefore takes a grave view of the practice which some medical authorities adopt¹⁹ of informing the couple that the child will be legitimate if the husband is registered as the father, and of demanding such registration although it constitutes an offence. Apart from the weighty arguments in favour of children being in a position to know their parentage, he would have expected a less cavalier attitude towards the formidable Perjury Act, which is infringed by the practitioner giving such advice as well as by the parent. If, on the other hand, the father's name is not stated the child's illegitimacy is patent to everyone who sees the certificate. This is a heavy price to pay for a badly wanted child, not to mention the price paid by the child later.

If there is a will or settlement creating an interest in property in favour of the "heirs of the body" of the couple, or if a legitimate child of theirs would inherit a title, they may be faced with the alternative of disclosing the child's illegitimacy or of committing a fraud upon the person who would benefit in the absence of legitimate offspring. In the latter event the medical practitioner who had brought about the conception might find himself involved in the subsequent proceedings. Dr Robert Forbes,²⁰ reviewing the subject before the Medico-Legal Society in May, 1944, displayed the forms of consent drawn up by Messrs Hempsons, the solicitors to the Medical Defence Union, and approved by the Council of the Union. These forms contain an assurance that the birth of the child will not defeat the claims of any person to any titles, estates, interest, or fund. Mr J P Ashworth, judging from his address to the Public Morality Council's conference, would place little reliance on such a document. He states definitely that an assurance that no third party's interests will be overridden is not worth the paper it is written upon, for the husband and wife do not know the intentions of all the third parties, who may be unknown to them at the time, or the terms of the wills of various relatives. If the form is intended to convey an undertaking to see that the birth of the child will not defeat the claims of third parties it should express that meaning.

Mr Willink makes the further point that concealment of illegitimacy operates as a fraud on the revenue, a higher duty is payable on the succession of an illegitimate than of a legitimate child. Moreover, the concealment of the truth from the child itself may make fraud against other persons almost inevitable, not only when property interests are concerned but whenever gifts or services are offered, as by the husband's parents on the implicit basis that the child is their son's. Even the consent of the husband and wife cannot be taken as absolutely proved by such a form as that of the Medical Defence Union. Experience in the United States suggests that the large majority of cases of AID raise no controversy, but a certain number go wrong, and then either the husband or the wife may deny having given a real consent. If this happens the practitioner may find that the signed document expressing consent, which he obtained before carrying out the insemination, is not so efficient a protection as he imagined. As Mr Ashworth pointed out, if the degree of consent is brought into issue the doctor might find himself charged with rape or with a serious assault. The introduction of a nurse as a witness to the consent of the parties, and as a signatory to the document embodying it, might help the doctor in legal proceedings but might not be very effective in forestalling them. Another serious result, sociological as well as legal, of the practice of AID on a large scale might be that since a single donor may father a large number of children the chance of their mating together incestuously would become appreciable. These legal problems, and many others which have been suggested from time to time, show the need for legislation to govern a practice which, whatever the objections to it, seems bound to become socially important. The medical practitioner desires to help his patients in every possible way, and evidence is not lacking that in a number of cases he can give substantial help by artificial insemination. It is neither just nor desirable that he should do so at such risk as the recent discussions have disclosed. He has a right to statutory guidance and protection.

RESHAPING THE CURRICULUM

During the past two years the General Medical Council in private sessions has been preparing new recommendations for the medical curriculum, these have now been published and are summarized on another page. It is important in this connexion to bear in mind the relation of the Council to licensing bodies and medical schools. The Council makes recommendations only, it does not prescribe a curriculum to be imposed on students. Indeed, there is no such thing in this country as a medical curriculum in the sense of one uniform course of study which all students must undergo and one examination portal through which they must all pass. Qualifications are granted in the United Kingdom and Eire by eighteen universities, two medical corporations acting severally, and three examining boards on behalf of seven other corporations. Any recommendations of the Council are directed only to maintaining certain minimum standards below which any curriculum must not be allowed to fall. The Medical Acts of 1858 and 1886 so far as they indicate standards to be attained by students and examination, furnish only general and abstract directions, and the Council has held it to be its duty to translate

¹⁸ *Practitioner* 1947 158 349

¹⁹ Barton Walker and Wiesner *British Medical Journal* 1945 1 40

²⁰ *Med leg criminol Rev*, 1944 12, 138

these abstract references into concrete terms. That is all that the recommendations imply.

In framing the new recommendations, which replace those of ten years ago, the Council has taken note at every point of the proposals of the Goodenough Committee, and has incorporated some of these proposals, notably one for a three months' transitional course between the pre-clinical and clinical periods the better to enable the student to carry into the clinical work awaiting him the methods of scientific thought and criticism which he has so far acquired. The Goodenough Committee was anxious to shorten the curriculum to 4½ years, but the Council, after careful deliberation, holds that five academic years is the minimum period for the acquirement of the necessary knowledge and skill.

The recommendations concerning the main subjects are not greatly altered. The number of cases of labour to be attended by the student in midwifery is reduced from twenty to twelve, but it is laid down that the student must attend during the whole course of labour and not merely at the end of the second stage, and that each delivery must count only to one or at most two students—in other words, that not more than two persons, either two medical students or one student and one pupil midwife, should receive credit for attendance on any case of labour. The principal changes are in the new subjects, or subjects whose boundaries are being swiftly extended—paediatrics, psychiatry, social medicine. The Council recommends that paediatrics be recognized as a major subject, and it is specified for the first time under a separate main heading. Similar headings are given to psychiatry and to after-care and rehabilitation. The Council also draws the attention of the schools to the consideration that more thorough investigation of so-called chronic sickness would restore many patients to a happier and useful life and reduce the bedridden institutional population. "Social Medicine and Public Health" is given a separate heading. Social medicine is ill-defined, the Goodenough Committee held it to include disease prevention, promotion of health, the effect on health of social environment and heredity, and the communal aspects of health and sickness. It is a subject on which for a long time to come there will be wide differences in the teaching—its boundaries and emphasis—given in the different schools, and the Council holds, with the Goodenough Committee, that an ample measure of discretion should be left to the schools to determine for themselves how far the instruction of students in the subject should be carried. The recommendations as to professional examinations differ in some details from those hitherto obtaining but here again most of the modifications appear to be designed to leave a larger discretion with the examining bodies. The Council by some regarded as a rigid and pedantic body, believes in preserving elasticity in medical education, encouraging emulation between the teaching institutions, and maintaining the individuality of the universities and corporations. The new recommendations leave to them an increased degree of initiative as compared with the old.

POTASSIUM THIOCYANATE FOR HYPERTENSION

The treatment of essential hypertension remains unsatisfactory. As Dr Evan Bedford observed in a discussion at the Royal Society of Medicine (reported elsewhere), the most important cause of death in hypertension is heart failure. Spontaneous cure occurred in 5.4% of Bechgaard's series of 1,000 cases followed up for ten years.¹ Mild and moderate cases usually show a gradual but significant fall in basal blood-pressure when confined to bed for one to

six weeks, but soon regain their original pressures when they return to work. If such patients can obtain more rest and relaxation their symptoms may disappear and their blood pressures may remain at lower levels, especially with the aid of sedatives and a light diet. The results of carefully controlled treatment along these simple lines should form a basis for assessing the value of more active therapy, unfortunately such results are rarely published. Of the more active methods recent interest has centred round the Smithwick operation, but thiocyanate still has its advocates, and the case for its use is presented in this week's *Journal* by Watkinson and Evans.

It should be remembered that Pauli,² who is usually credited with the introduction of thiocyanate as a hypotensive agent, first used the drug in the hope that it would prove better than bromide in relieving the symptoms of neurosis and reported singular success in this respect. The effect of sedation on labile hypertension is well known, and if thiocyanate merely acts as a sedative it would be better replaced by a less toxic substance. It would be helpful if further reports dealt more with its mode of action than with the clinical results of its empirical use, with its toxicity, or with its effective blood level, all of which have become sufficiently well known and may be summarized as follows. Clinical benefit and a significant fall in blood pressure may be expected in about 60% of cases of persistent hypertension, according to Watkinson and Evans, especially in the younger labile group,³ and rarely in malignant or chronic nephritic hypertension.

The potassium salt is usually given by mouth in peppermint water in initial doses of 0.1–0.2 g (1½–3 gr) three or four times daily after meals until a serum level of 5–8 mg per 100 ml is reached. If this proves ineffective the higher dosage is continued until the serum level is 8–12 mg per 100 ml. The maintenance dose is commonly 0.1 g three times daily. Control of dosage by means of weekly blood-level estimations was introduced by Barker,⁴ who regarded anything above 20 mg per 100 ml as dangerous, and anything below 15 mg as safe. The normal thiocyanate blood level in untreated subjects with or without hypertension is 0.3 mg per 100 ml.⁵ Later work indicates that serious toxic symptoms may begin at concentrations less than 15 mg per 100 ml, and that it is best not to exceed the lowest effective blood level.⁶

Toxic symptoms include weakness, anorexia, indigestion, nausea and vomiting, limb pains, impotence, dermatitis, purpura, goitre, thrombophlebitis, mental lethargy, and confusion. In fatal cases dysarthria, verbal aphasia, clonic convulsions, delirium, hallucinations, and mania have usually preceded death, which has occurred within three to nineteen days. The question of chronic poisoning after five to ten years' continuous therapy was raised by Wald, Lindberg, and Barker,⁷ who observed progressive anaemia and emaciation in some cases.

It is usually stated that the drug is unsafe in patients over 60, in subjects with hypertensive encephalopathy or previous stroke, and in those with impaired renal function, but Watkinson and Evans observed no ill effect in 15 patients over 60 years of age, or in 16 cases of malignant or chronic nephritic hypertension. These authors recommend potassium thiocyanate for hypertensive subjects with headaches and giddiness, for those with diastolic blood pressures persistently over 130 mm Hg, and as an adjunct to the Smithwick operation. They found it of no value for the relief of angina pectoris or intermittent claudication, or for the treatment of hypertensive heart failure.

REVISION OF MEDICAL CURRICULUM

NEW RECOMMENDATIONS BY G.M.C. SOME "GOODENOUGH" PROPOSALS EMBODIED

The General Medical Council has adopted a new series of recommendations for the curriculum, replacing those of 1936-7. The new recommendations are published¹ with a lengthy introduction setting out their bearing upon the criticisms of the curriculum made in 1944 by the Inter-Departmental Committee on Medical Schools (the Goodenough Committee). The Council would in any event have undertaken a revision after the end of the war, but the task was accelerated by the Goodenough report, which urged a drastic overhaul. In September, 1944, the then Minister of Health asked the Council whether early action could be taken, and in November of that year the Council set up special committees for the purpose. These have been in close communication with the licensing bodies and medical schools and a delegation, including the President of the Council, has visited Canada and the United States, where much useful information has been obtained. Drafts of the new proposals were circulated to the interested bodies last year, and the recommendations were adopted at a recent special meeting of the Council, little more than two years after the work was begun.

The first task was to decide to what extent the severe criticisms by the Goodenough Committee were valid and ought to have effect in the new recommendations. The Council repeats several times in this report that it has no power under existing law to visit the medical schools, and therefore is not in a position to confirm or to confute from its own observations the conclusions of the Goodenough Committee on this or that point but certain of the Goodenough proposals have been accepted and reasons are given for the non acceptance of others.

Length of the Curriculum

The Goodenough Committee expressed a concern, which the Council shares, about the overloading of the curriculum, but the extent to which the matter can be remedied is subject to the limitation of the Council's powers under the Medical Acts. The most it can do to lighten the load is to ensure that nothing in its recommendations encourages the retention of what is unnecessary or premature for the instruction of the student. It believes that in these new recommendations only those subjects are included which it is essential for the safety of the public that the student shall learn.

Notwithstanding this, the Council cannot agree with the Goodenough Committee that the total normal length of the course of training leading to the final examination should not exceed 4½ years. The disadvantages of a long curriculum are fully recognized but in the Council's view the requisite knowledge and skill cannot be acquired in less than five academic years, made up of a period of pre-clinical studies of not less than five academic terms, an introductory or transitional clinical course lasting three months, and a period of clinical studies covering at least 33 months.

No substantial alteration is made in the recommendations for general and pre medical education adopted in 1937.

Every student should pass (1) a recognized primary examination in general education, and (2) an examination or examinations in physics, chemistry, and biology (both theoretical and practical in all three subjects).

The Goodenough Committee recommended that the teaching of these sciences should form part of the pre-clinical period, but the Council has to take a more narrow view and all it can properly attempt is not to include anything which would impede a broad general education and to ensure as far as possible a balance between general and scientific subjects.

Introduction to Clinical Study

During the five academic terms of the pre-clinical period

Instruction should be given in human anatomy and physiology, including (1) dissection of the whole body (2) anatomy of the living body, including radiological examination (3) principles of physiology (4) use of instruments employed in diagnosis (5) histology (6) (7) (8) elements of human embryology, of genetics,

and of psychology. Every effort should be made to secure close correlation between anatomy and physiology, and to stress the importance of these subjects in their clinical application.

Certain aspects of social medicine and public health in the Goodenough Committee's opinion, might be taught during the pre-clinical period but the Council prefers these subjects in broad general terms to be included in the clinical period. The Council adopts the Goodenough recommendation for a three months transitional period to enable the student to appreciate the relation between his pre-clinical and clinical studies.

During this period a course of instruction in methods of clinical examination should be given. Instruction in the elements of pathology and bacteriology and of pharmacology may also be given during this period or during the pre-clinical period or partly during the former and partly during the latter.

Instruction in Medicine and Surgery

Coming to the period of clinical studies, the recommendations set out that the course in medicine and the course in surgery should include systematic instruction in the principles and practice of each, and a medical and a surgical appointment in the hospital wards and in an out-patient department, each appointment for six months, including not less than one month's residence. In medicine instruction is to be given in the following subjects:

Acute infectious diseases, tuberculosis, diseases of the skin, venereal diseases, radiology in its application to medicine, dietetics, nursing, physiotherapy. In surgery: diseases of the ear, nose, and throat, and of the eye, orthopaedics, dental diseases, radiology in its application to surgery, and a course of theoretical and practical instruction in the administration of anaesthetics.

It was contemplated by the Goodenough Committee that the student in medicine should spend about four months in hospital appointments after the introductory clinical course and a further month in the first half of the final year as senior clerk. The Council, however, thinks it undesirable that any reduction should be made in the six months period as specified in its former recommendations but it is clear that the student may during this period also hold an appointment in a medical out-patient or equivalent department. The Council agrees with the Goodenough Committee that it would not be desirable, even if practicable, to include teaching expressly intended to equip the student to undertake major operative surgery, but it is regarded as a not remote possibility that the student, as soon as he is entitled to practise, may be called upon to undertake minor operative surgery and therefore instruction in that subject can not be safely omitted. "Practical instruction in minor operative surgery on the living" is therefore to be part of the instruction in surgery. The Council suggests that students should not spend more time in the operating theatre than is required to ensure familiarity with common surgical conditions, their recognition, and treatment.

Student's Attendance at Labour

The Council cannot accept the assumption of the Goodenough Committee that the unrestricted title to practise midwifery conferred on all registered medical practitioners should now be restricted if not in law, at least in fact, but the Goodenough Committee also held that such a course as is outlined in the Council's recommendations is necessary even though future general practitioners may refrain from dealing with abnormal conditions unless they have had adequate postgraduate training. The recommendations (summarized) are that the instruction should include:

Systematic instruction in principles and practice of midwifery and gynaecology including anatomy, physiology, and pathology of pregnancy and labour, and clinical instruction in midwifery, infant hygiene and gynaecology, with attendance on the practice of a maternity hospital or maternity wards and on in-patient and out-patient gynaecological practice over a period of six months.

This period is to be later than the medical and surgical appointments, and earlier, if possible, than a clinical clerkship in paediatrics.

Throughout the six months the student should receive instruction in antenatal and post-natal care, management of the puerperium and care of the newborn infant. At least two thirds of the hour of clinical instruction should be devoted to instruction in midwifery and infant hygiene. Not less than two months should be spent by the student in residence during which he should attend not less

¹ London: Constable, 2s. 6d.

The Goodenough Committee recommended a period of 30 months, including 8 weeks' holiday.

than 12 cases of labour under proper supervision, the first five at least in lying-in hospitals or wards. At his qualifying examination he must produce a certificate showing that he has attended such cases of labour, that he has written an adequate history of them, that in each case he has been in personal attendance on the patient during the whole course of labour and that he is not credited with any case which appears on the certificate of more than one other medical student or on that of more than one pupil midwife.

In its recommendations issued ten years ago the Council specified 20 as the number of cases of labour a student must attend. It is agreed that this number is not seldom unattainable, especially in metropolitan schools and it has been reduced to 12.

The Council is satisfied that if strict compliance is required with the provisions of the new recommendations as to the supervision of students during their attendance on cases, the restriction in the sharing of cases and the amount of attendance on each case—[‘the whole course of labour,’ and not merely the end of the second stage]—any disadvantage which may be entailed by the reduction of the minimum number of cases to be attended will be amply compensated.

New Major Subjects

Three subjects—namely paediatrics or child health, psychiatry and social medicine—received special prominence in the Goodenough report because of the developments that are necessary in the training provided in these subjects. That report expressed the view that generally in the medical schools the teaching about children has been inadequate and only faint interest has been taken in the subject. Here again the Council maintains its non-committal attitude, it is not in a position to confirm or to confute general statements but it agrees as to the importance of paediatrics in the curriculum and that it should be recognized as a major subject.

Instruction in paediatrics should include (1) systematic instruction in principles and practice (2) a three months clinical clerkship including one month's residence (3) instruction in the care of the newborn infant and in the diseases of the neonatal period, given during the course in midwifery (4) attendance at not less than six sessions in a child welfare centre, and (5) attendance at school medical and child guidance clinics.

For the first time the subject of psychiatry also is specified under a separate main heading. Here again the Council agrees with the Goodenough Committee alike as to the importance of the subject, the desirability that instruction be concentrated on potential rather than on established disorders of the mind and the need for co-operation between teachers of psychiatry and teachers of other clinical subjects.

Instruction should be carried out mainly in a psychiatric out-patient department but clinical demonstrations should also be given at a mental hospital and at a mental deficiency institution. A course of systematic lectures should be given and the attention of the student continuously directed to the relationship between physical and psychological aspects of disease.

Another subject specified under a separate main heading is Methods of After-care and Rehabilitation, and without making a separate heading attention is drawn to the importance of chronic sickness. Social medicine is also a new major subject but the Council agrees with the Goodenough Committee that the scope of instruction should be free from any attempt at rigid definition and susceptible of modification in the light of experience.

Instruction should be given in the principles of preventive medicine including epidemiology, the influence of heredity and environment including occupation on health and disease, the principles of health education and the functions of central and local authorities and voluntary organizations.

There will be room for differences between the various bodies on such questions as whether if instruction be given in sex hygiene it is best given by an experienced general practitioner.

The recommendations concerning instruction in pathology and bacteriology and pharmacology and therapeutics appear to remain as they were. In forensic medicine the recommendations are unaltered save for one omission. In its former recommendations the Council suggested that instruction in the legal and ethical obligations of practitioners should be given by some person having practical knowledge of the subject (that is to say normally an experienced general practitioner), but it is

anxious not to dictate to licensing bodies and schools, and it is confident that ample experience is now available to assist them to select suitable instructors.

Professional Examinations

The recommendations for professional examinations have also been rearranged but altered only in relatively minor detail. The examination in each subject should include written and oral tests and in the case of clinical subjects a clinical test is a clearer and more comprehensive statement of what was indicated in the earlier recommendations. The requirement that in all written examinations an average of at least half an hour should be allowed for a candidate to answer each question has been dropped, here as in several other matters discretion is left to the examining bodies. A recommendation that at least two examiners should participate in the adjudication of all written papers is substituted for the existing one that the marks should be a joint adjudication. Hitherto, in theory, the answers of all candidates have been read by two examiners, but in practice except in the case of candidates on the borderline they have often been read by only one. A comment of the Council's Inspector in Medicine that the requirement that two examiners shall participate is not uniformly interpreted in the oral and clinical examinations has led to a new recommendation—that at least two examiners should be present at the examination of each candidate and the marks should be a joint adjudication. It is added that examinations in all clinical subjects should include adequate practical tests: this follows a report by one of the inspectors that practical tests for example urine analysis are frequently not included. A former provision that candidates who obtain less than 30% of the marks in any subject should be remitted for a longer period than three months has been dropped, here again discretion has been left to the examining bodies. The recommendation concerning the scope of examination has been expanded.

“Candidates should be required to pass examinations in the following subjects (1) Medicine, surgery, and midwifery and gynaecology including the subdivisions of these subjects specified in the foregoing recommendations as to professional education (2) Paediatrics (including infant hygiene and child welfare) psychiatry and therapeutics. The examinations in these subjects may be separate examinations or may form part of the examinations in medicine, surgery, and midwifery and gynaecology (3) Social medicine and public health, forensic medicine, pathology and bacteriology, pharmacology.”

This is intended to give effect to the view of the Council that in the final or qualifying examination in medicine, surgery, and midwifery and gynaecology candidates should be examined both in these main subjects and in their subdivisions, and discretion is left with the licensing bodies and examining boards to examine in paediatrics, psychiatry, and therapeutics either in the final and qualifying examination or in previous separate examinations. The Council's Inspector in Medicine has been impressed most favourably by the introduction of a separate examination in psychological medicine and psychiatry in certain centres and the Inspector in Midwifery welcomes the recent introduction of separate examinations in paediatrics.

A further recommendation provides that no part of the final or qualifying examination, not only in medicine and surgery but in midwifery and gynaecology shall be taken before the end of 30 months of clinical study. The recommendation which this displaces contemplated that the clinical and practical examination in midwifery and gynaecology might be taken in advance of the rest of the final in midwifery and in advance of the final in medicine and surgery. It is thought that the new recommendation will enable licensing bodies to safeguard themselves against premature attempts on the part of students to pass parts of the final and will also safeguard the candidates against a degree of overloading of the final which in the words of the Inspector in Medicine ‘renders some examinations a test of physical endurance rather than proficiency’.

A recommendation which has hitherto obtained is that whatever be the method of entry for the final examination, all candidates should be required to complete the three portions of the final examination within a period of 19 months. After careful consideration the Council has come to the conclusion that this does not in fact secure to the public the safeguard

which it purports to offer and that it is better to leave the examiners with discretion to reject candidates who appear not to attain the required standard of proficiency. The recommendation therefore has not been retained. The recommendation that in the three primary subjects no candidate should be allowed to pass who fails to obtain 50% of the marks assigned to the clinical examination is repeated but certain other minima suggested in that recommendation have been dropped. They are considered matters proper to be determined by the examining bodies, and indeed the general effect of such alterations as have been made in the conduct of examinations is to leave these bodies with a larger discretion.

Reports of Societies -

MANAGEMENT OF PATIENTS WITH ESSENTIAL HYPERTENSION

In the Section of Medicine of the Royal Society of Medicine on April 22 Dr MAURICE DAVIDSON presiding a discussion took place on the management of patients with essential hypertension.

Dr GEOFFREY EVANS discussing aetiology said that in some of these cases there was undoubtedly a constitutional disease, to which at least there was an inherited predisposition, in others family influence and environment might determine the development of hypertension. Thus considerable understanding of a patient was necessary before giving him advice as to his manner of living but at least it should be remembered that living was an art and nowadays something of a problem. In the emotional background of these people there was often fear and apprehension, thus it was helpful to cultivate a sanguine attitude of mind towards them. Exhaustion aggravated hypertension even if it did not cause it, rest and relief from emotional tension were important. As for sedatives, he criticized the extravagance with which phenobarbitone and the barbiturates were prescribed. Exercise and a little alcohol might do good, those with peripheral congestion might benefit from venesection, and those overweight by weight reduction. Those were the ordinary conservative measures of approach for patients with essential hypertension.

Value of Potassium Thiocyanate

Potassium thiocyanate, Dr Geoffrey Evans continued, was of undoubted value in the relief of headache and giddiness, and in some patients it improved their feeling of well-being. In the minority there was a fall in blood pressure. He mentioned the case of a scientist aged 42, who had hypertensive retinopathy and was given potassium thiocyanate. He had now been relatively well for five years except for a recurrence three years ago when he gave up the treatment for a time and his headaches immediately returned. He was now, with this treatment, able to do rather more than two-thirds of his day's work. It was strange that after 11 years' experience of potassium thiocyanate there should still be such difference of opinion as to its value. He believed the reason to be as follows. Hypertension was caused by generalized hypertonia in the systemic circulation and many of its symptoms and complications were brought about by localized vascular spasm. If such spasm caused headaches and functional disturbance the patient might have these symptoms for years and apparently be no worse. But in some patients there followed a structural reaction to the functional change, this took the form of arteriosclerosis with irreversible changes leading to thrombosis and other sequelae. As physicians they had to determine by investigation whether the arteriosclerotic disease was active or quiescent. Their patients would do well not necessarily according to the way in which it was possible to control the symptoms—the headaches, giddiness and so on—but according to the nature of the arteriosclerosis. In some the arteriosclerosis might be quiescent and perhaps disappear, in others once started, it was steadily progressive. Patients might respond not only symptomatically but in their blood pressures to potassium thiocyanate, and show only moderate hypertension and yet develop retinal thrombosis because the disease was not controlled. So far as he knew there was no method, other than the conservative

measures he had detailed, of preventing the active phase of arteriosclerotic disease developing. It was on this that the prognosis turned and it could be evaluated only by watching a patient with arteriosclerotic disease treated on conservative lines over a period of ten or twenty years.

Surgical Measures for Relief of Hypertension

Mr A DICKSON WRIGHT said that hypertension was one of the most inexact and bewildering of diseases. One of its types was secondary to migraine. Sufferers from migraine were four times as likely as the ordinary person to get hypertension. Another group consisted of children with headaches and dizziness which would be described as functional if they occurred in the adult. The method of dealing with hypertension by means of surgery lay in one of two directions. One method was to attack the adrenals, but no very large measure of success had been achieved. The other method was to attack through the sympathetic system. Mr Dickson Wright showed by means of a film the procedure he favoured which was Adson's operation of sympathectomy and partial adrenalectomy. This operation should not be undertaken if the patient was over 50 or had a high blood pressure which did not subside after rest in bed and sedation. Of bad significance were high diastolic pressure and high pulse pressure. The pale hypertensive had a much worse prognosis than the bucolic subject. Women did better than men in every respect. But if a case was around the forties and there were headaches and other symptoms of hypertension one should not be too strict in looking for contra-indications. While his own predilection was for the Adson operation, there were others which were employed by other surgeons, and at the Mayo Clinic he was informed that the results were considered to be slightly better with the Smithwick operation. While in his hands Adson's operation had seemed to have a definite value, he never trusted himself to compile statistics of results. There was a certain percentage of failures, but no one was the worse for this operation and it had practically no complications.

Dr C WYNDHAM described some recent work carried out at the British Postgraduate Medical School on peripheral mechanisms which affect blood pressure. These mechanisms were skin tone, muscle tone, and splanchnic tone, which affected not only total peripheral resistance but also venous tone, and this in its turn affected the pressure with which the blood returned to the right heart and thus affected the cardiac output. He described in this relation the action of sympathectomy.

Mr H J B ATKINS asked whether there might not be some danger in the sudden reduction of blood pressure after sympathectomy. One of Mr Dickson Wright's two fatalities in his large series of cases was due to cerebral thrombosis and in a very small series of the speaker's a patient had a retinal thrombosis on the fourth day and went blind in one eye. If this complication of postoperative thrombosis was a serious danger he wondered whether it might not be wise to institute routine heparinization.

A "Forty-hour Week" for the Heart

Dr EVAN BEDFORD said that by far the most important cause of death in hypertension was heart failure. Over 60% of patients with persistent hypertension had heart failure of one form or another compared with less than 20% dying of cerebral vascular accidents. Therefore the management of the patient should be directed especially to the care of the heart. Probably half of all cases of organic heart disease seen in practice were due wholly or in part to essential hypertension. If the rate at which the heart enlarged were measured it would be found to be almost imperceptible from year to year. In cases in which he had made measurements over a period up to 14 years the average increase in transverse diameter was less than 2 mm annually but at a later stage a rapid enlargement might take place. Coronary disease must always be remembered as a frequent complication of hypertension. A fair number of cases had combined coronary and hypertensive heart disease. Treatment should be directed towards preventing or delaying the enlargement of the heart and when the heart was enlarged towards preventing or delaying heart failure. The crux of treatment was the control of the hypertension itself but as yet no sure way of control was known. No drug was capable of permanently lowering the blood pressure in a case of essential

hypertension. Occasional successes were obtained with thiocyanate but in the majority of cases thiocyanate was either too toxic or too disappointing to be any solution of their problems as a whole. The hypertensive patient must be taught to live slowly. A forty hour week should be prescribed for the heart. By judicious advice much could be done to delay the progress of cardiac enlargement and the onset of heart failure. As for surgery it was most difficult to assess the results from the statistics. It was unfortunate that results were given in terms of reduction of diastolic pressure which meant very little. In terms of the humoral theory of hypertension surgery was an irrational procedure but it might still be an effective one. It was not a cure for hypertension but at the best it could lower, sometimes appreciably, the blood pressure level and diminish the burden on the heart.

Mr. DICKSON WRIGHT said that the incidence of clotting in the eyes or brain after these operations of sympathectomy had been low and rather comparable with the incidence of femoral thrombosis after abdominal operations. He had not yet thought of giving heparin. It was the load on the heart which killed the patient. They were too prone to think of cerebral haemorrhage but the real mischief was the slow wearing out of the myocardium.

MEDICAL PHOTOGRAPHY

A meeting of the Medical Society of the L.C.C. Medical Service was held at County Hall on April 3 to discuss the uses of photography in medicine.

Dr. J. E. MCCARTNEY stressed the value of accurate and immediate recording of medical cases. Lesions were often fleeting, appearances changed rapidly, patients might recover or die and information not recorded at the time might be impossible to get later. In a written record the clinician put down only what he saw. A sketch might add a few more details, but a photograph would reveal not only all the clinician saw at the time but perhaps further information for other observers. Accurate photographic records were valuable both for present and for future investigations. Medical photography should be taken seriously. It required adequate modern equipment and a skilled staff. Medical photography was so specialized and involved such varying conditions of work that it was imperative to employ a first-class, well trained, well paid photographic technician.

Each patient presented a different problem, and special pieces of apparatus and a number of different lenses and cameras were necessary to cover the whole range of clinical photography. Special equipment was again required for biopsy or post mortem specimens. To show the correct dimensions of the specimen a centimetre scale or similar measure should be placed beside it. Miniature photography was useful for recording case papers, documents, reprints, books, etc. This had been specially developed in America with elaborate and costly apparatus.

Dr. McCartney went on to say that in America during his recent visit he had seen the latest developments of colour work and printing. Illustrations demonstrating the value of coloured backgrounds for throwing the subject into relief were shown. Cinephotography was invaluable for recording movement, such as gait and the progress of orthopaedic and similar cases. The use of colour in the cinephotography of operations was demonstrated and the value of sound film for teaching purposes was stressed. A 16 mm film showing parts of various medical films in black and white and in colour made by Mr. J. E. Andrews, the L.C.C. medical photographer, was then demonstrated.

Dr. GUNN emphasized the value of cinephotography for teaching purposes but thought it should only be considered in the case of operations or manipulations as an adjunct to direct clinical teaching. Mr. MATTHEWS remarked that though colour photography had considerably improved films of operations, it was still very difficult to see important details owing to the over-exposure due to reflection of light from the tissues.

Dr. McCartney raised the question of film-strips, suggested that for teaching purposes film-strips were more useful than still motion films as they could be arranged beforehand to show all the points and only those points which the lecturer desired to stress. He also questioned the value of taking films

of operations. It was impossible to learn to operate from the film and while it might make a pretty picture, there were many other aspects of medicine in which a film could be of much greater value.

Mr. PIERCEY, admitting that part of the film shown was of himself doing a thyroidectomy, said that the reason for having this film taken was to preserve a record of Mr. C. A. Joll's technique and particularly of his exposure and ligature of the inferior thyroid artery. He thought that films of operations showing special technique were of great interest to surgeons and others. Mr. ANDREWS said it was quite easy to get film-strips made by commercial firms. The cost was about 1s a picture and projectors were available from about £8 upwards. He thought that slides were more generally useful. The order of showing them could be altered and they stood up to heat much better than film-strips.

Correspondence

State Medical Service in New Zealand

SIR—New Zealand has enjoyed a partial State Medical Service for the past 10 years. In the current issue of *St. Mary's Hospital Gazette* Mr. A. E. Porritt—a New Zealander coming to England as a Rhodes Scholar to study medicine 23 years ago—gives a "dispassionate review on things medical in New Zealand" which he observed during a recent visit to that country. He remarks that although New Zealand is one of the most beautiful and naturally endowed countries in the world to-day "it is even more full of petty restrictions in its administration than this country." He sums up his conclusion on the medical services in these pregnant sentences: (a) A slightly improved all-round service for the public—during business hours. To get a doctor in New Zealand after 6 p.m. and over week-ends is not an enviable task. (b) A definite falling off in the standard of medical practice from both ethical and clinical viewpoints. This is a consensus of opinion from all branches of the profession. (c) A growing and already appreciable dearth of specialists—and this in a country where the proportion of meriting higher degrees was previously exceptionally high.

We have been warned!—I am, etc.

London, S.W.1

E. GRAHAM-LITTLE

Reiter's Syndrome

SIR—I am particularly interested in the claim made by Dr. R. R. Willcox and his collaborators (April 12, p. 483) that gold salts (myocrisin) were curative in two of their cases of Reiter's disease. As reported in an address to the Medical Society for the Study of Venereal Diseases in May, 1944, I was at that time carrying out treatment with myocrisin on a typical case of Reiter's disease with non-gonococcal urethritis, bilateral conjunctivitis, polyarthritides, and keratoderma blennorrhagica (Case 20 in the series) in spite of the fact that no pleuropneumonia-like organisms had been cultivated from the urethral, conjunctival or skin lesions. I had read the paper of Findlay *et al.* in which it was stated that organic gold salts protected rats and mice from developing arthritis after injection in the pad with pleuropneumonia-like organisms and the drug was prescribed on the supposition that the inclusions seen in my cases may have been the granular phase in the development of these organisms. No beneficial effects followed gold therapy in this and two further cases under my care. King in the treatment of Reiter's disease with the Simpson-Kettering hypertherm gave several cases injections of myocrisin during fever and the results obtained were no better than with fever alone. I was interested to note that in Case 1 of the authors' there was a fall in the blood sedimentation rate during treatment as in none of my cases has this ever been observed. In fact I find the test of little value in the assessment of progress. In one apyrexial case now under my care that has already received five injections of myocrisin the B.S.R. which was originally 30, has risen steadily each week and is now 41.

It is possible that the beneficial effects of gold therapy in the cases recorded by Willcox *et al.* were non-specific and due to the rise in temperature which sometimes occurs after the

ions This was definitely so in my cases for which hourly temperatures are recorded for 12 hours after each injection, the apyrexial case to which reference has already been made temperature registered 101.6° F (38.7° C) three hours after first injection 102° F (38.9° C) ten hours after the second 99.6° F (37.5° C) seven hours after the third 99.2° F (37.3° C) nine hours after the fourth and 99° F (37.2° C) eight hours after the fifth. A further patient who has just started a course developed a temperature of 100.2° F (37.9° C) three hours after the first injection. All the temperatures returned to normal in an hour or just over an hour and could have been overlooked with a 4 hourly chart. I have observed on several occasions that mild fever induced by intramuscular injections of aolan effects rapid cures in these cases.

The aetiology of the disease is still uncertain. Pleuropneumonia-like organisms have been cultivated in the urethral discharge of 14 out of 84 men suffering from uncomplicated non gonococcal urethritis in the cervical secretion of 10 out of 42 women with cervicitis, and in only 3 of 30 of my cases of Reiter's disease. Urethral cultures were also positive in my first case treated with gold eighteen months after apparent cure, and it is worth noting that there had been no subsequent sexual exposure. An examination carried out before the first morning micturition did however show the existence of a mild residual abacterial urethritis which may have persisted since the original illness. Cultures were negative in the synovial fluid of two and in the conjunctival secretions of three of my cases. Examination of female contacts of 5 cases in which pleuropneumonia-like organisms were isolated in the urethral discharge yielded negative cultures, but elementary bodies were seen in two. The majority of my cultural examinations have been carried out by Henderson Begg and Edward.

It is possible that the disease as I originally stated, is due to a virus. Primary herpetic stomatitis of infants and young children is caused by the virus of herpes simplex and a virus has recently been shown by Buddingh to be responsible for a similar disease associated with diarrhoea in children. Strains of the virus are maintained by serial passage from cornea to cornea of rabbits, but unlike primary herpetic stomatitis no inclusions have been found. In the discussion following Buddingh's paper on this subject Sabin stated that these inclusions would probably be demonstrated in serial sections. On this occasion Dodd also reported that she had obtained positive corneal inoculations in rabbits with vaginal swabs taken from the mothers of the children suffering from the disease. Buddingh had observed similar results with the urethral discharge and oral and conjunctival secretions of a typical case of Reiter's disease.

There would seem therefore to be definite room for doubt whether pleuropneumonia-like organisms are the aetiological factor in Reiter's disease. I consider too that the efficacy of gold therapy in the treatment of this disease requires further investigation. In view of its dangers I have not used this form of therapy in the treatment of uncomplicated abacterial urethritis (usually a very mild disease) in which these organisms have been isolated—I am, etc.,

"Sulpha-Combination"—A New Chemotherapeutic Principle

SIR—In the article on 'Sulpha-Combination'—A New Chemotherapeutic Principle by Drs A. Rune Frisk, Gösta Hagerman, Sture Helander, and Bertil Sjogren (Jan 4 p 7) reference is made to my work on the same subject in a form which creates the erroneous impression that I have suggested only the use of a mixture of sulphathiazole and sulphadiazine. I therefore take the liberty of bringing the following facts to your attention.

My publication to which reference is made by the Swedish investigators appeared in print in January 1945—that is one year and three months before these authors published any of their experimental or clinical results with a combination of three sulphonamides and two years before their article appeared in your *Journal*. The title of my publication—"Inhibition of Drug Pre-

cipitation in the Urinary Tract by the Use of Sulfonamide Mixtures. I. Sulfathiazole-Sulfadiazine Mixture (*Proc Soc exp Biol N.Y.*, 1945 58 11)—clearly indicates that the general principle of a sulpha combination was investigated and that the sulphathiazole-sulphadiazine mixture represented only the initial phase of this work. This point is further emphasized in Table I of my paper containing solubility figures of seven different sulphonamide combinations, one of these consisting of as much as four separate constituents. In addition several statements in the text of this publication leave no doubt about the recognition of the general principle and the direction of further research.

I quote: "Since even closely related sulphonamides, when present simultaneously in the same solution, do not influence each other appreciably with regard to their particular solubilities the danger of intrarenal drug precipitation from the sulphonamides comprising the mixture should be only as great as if each compound had been administered alone, and in the partial dosage contained in the mixture."

Sulfathiazole and sulfadiazine were selected for the initial series of experiments, because these compounds are at present most frequently employed, have almost the same therapeutic indications, and cause renal complications in about the same percentage of cases. The findings of the solubility study summarized in Table I indicate that many other sulphonamide combinations should be investigated as to their ratio of renal toxicity and bacteriostatic activity. Since then I completed experiments on the combinations of sulphadiazine-sulphamerazine, and sulphadiazine-sulphathiazole-sulphamerazine early in 1946 and submitted my work to the American Medical Association in February, 1946 for presentation at its 95th Annual Session at San Francisco on July 3, 1946. The title of this presentation was 'The Prevention of Renal Complications by the Use of Sulfonamide Mixtures' (Announcements *J Amer med Ass* 1946, 131 306 and *ibid* 131 1141).

Further references to the general principle of sulphonamide mixtures can be found in three clinical publications. In the *Journal of Urology* 1946, 55 1 stated on p 565, "With regard to its potentialities and to possible future developments, however, treatment with sulphonamide mixtures seems to hold the promise of an efficiency which might dispense with the necessity of any other preventive measure." In the *Journal of Pediatrics* 1946 29 we explained on p 284 "Experimental work and preliminary clinical trials suggest that for the treatment of meningitis, sulfadiazine should be combined with a sulphonamide such as sulfamerazine, which diffuses better than sulfathiazole through the hematocephalic barrier. Our results suggest that the simultaneous employment of two or more sulphonamides should replace the use of single compounds, since mixtures combine a high therapeutic efficacy with a significantly lowered toxicity."

Flippin *et al* published 'An Evaluation of Sulfonamide Mixtures and Various Adjuvants for Control of Sulfonamide Crystalluria' in the *Annals of Internal Medicine* 1946 25 433. I quote from the discussion of this paper: "An alternative method, proposed by Lehr¹² avoids exceeding the critical concentrations at which crystallization will occur by using two or more sulphonamides simultaneously. Our preliminary observations indicate that this approach is as effective as the administration of sodium bicarbonate at the rate of 12 grams per day."

In summary then: The use of sulphonamide mixtures for the prevention of renal complications was conceived independently in our laboratory as the result of extensive animal experimental investigations on 'Methods which Inhibit or Prevent Intrarenal Precipitation of Compounds of the Sulphonamide Series' carried out since 1941. I published complete experimental proof for the validity of the sulphonamide mixture principle one year and three months before the Swedish investigators announced their new chemotherapeutic principle in *Nordisk Medicin* 1946 29 639 based on their first animal experimental study. Previous to this publication the authors, according to their own statement had done only preliminary clinical work with a mixture containing equal parts of sulphathiazole and sulphadiazine. Even if my publication to which reference is made by the Swedish authors was the only one available to them when their article was written they must have been aware of the fact that I did not merely suggest the use of a sulphathiazole-sulphadiazine mixture as the reference in your *Journal* implies but that I had offered valid animal experimental proof for this new concept of sulphonamide therapy. On the basis of the evidence presented I am forced to conclude, with regret, that the Swedish authors, in quoting my publication did not cite the facts properly and completely. Hence they have failed to give due credit to my work in this field—I am etc.

Vitamin Therapy *- its uses and limitations*

SAFER PREGNANCY

Although priority supplies of essential foods are allocated to pregnant women, there still arise cases in which anaemia, fatigue, debility indicate to the physician that all nutritive factors are not, in fact, being assimilated at the level of their physiological requirement. Pregnavite is designed to contain, in a single preparation, those factors most likely to be needed and in doses such as to meet the requirements of most women.

PREGNAVITE

A single supplement for safer pregnancy

The recommended daily dose provides

vitamin A	4 000 i.u.	vitamin E	1 mg	iodine	} not less than 10 p.p.m. each
vitamin D	300 i.u.	nicotinamide	25 mg	manganese	
vitamin B ₁	0.6 mg	calcium	160 mg	copper	
vitamin C	20 mg	iron	68 mg

METHYL-THIOURACIL B.D.H.

In the Treatment of Hyperthyroidism

Clinical experience is providing evidence that the methyl compound is less likely to cause agranulocytosis and is possibly more effective than thiouracil itself.

Methyl-thiouracil B D H should be prescribed, therefore, in preference to thiouracil whenever the use of the latter compound is considered. When the drug is used pre-operatively, it is advisable to give iodine in addition during the week immediately before operation in order to reduce the friability of the gland and the risk of excessive hæmorrhage in the operative field. Further details are available on request.

International System of Weights and Measures

SIR—In his interesting article on "The International System of Weights and Measures" (April 5, p 460) Dr J M Hamill makes out a clear theoretical case for the substitution of the millilitre (ml) for the cubic centimetre (cc). He expresses regret at the obduracy of our profession in adhering to the incorrect use of the cubic centimetre as a measure of volume. Unfortunately, perhaps, the mischief does not end there. The cubic millimetre (cumm) is universally used in the data of haematologists. As a metrical purist, would Dr Hamill advocate the substitution of the microlitre, and would he suggest a suitable abbreviation for this quantity?—I am, etc,

Manchester

DOUGLAS A K BLACK

SIR—Dr J M Hamill's article (April 5, p 460) is most interesting and valuable. I do not wish to discuss his suggestion that in spite of common usage the metric system should not be so called, but the rather more important question of the cubic centimetre versus the millilitre. Scientists use the cgs (or mks) system of measures for mechanical quantities, and, as its name aptly suggests, the fundamental units are the cm, g, and sec (or m, kg, and sec). Dr Hamill is absolutely correct in distinguishing between the cm³ and ml. But R T Birge (1941, p 102) says "The litre and millilitre are not units in the present cgs system, whose unit of volume is the cm³". All scientists quite reasonably, think of the size of a volume in terms of the sizes of its sides—that is, as a derived quantity in the cgs (or mks) system. If they wish to think thus they have the authority of so eminent a person as Prof Birge that they should use the cm³ as their unit of volume. It is a purely legal form (like the gallon) that the ml ever got started, scientists writing scientific articles should refer to the cm³ (which may perhaps be given the bastard abbreviation of cc) unless they are actually and significantly using the millilitre. If they be writing legal reports they should use throughout whatever odd units—yard, drachm, or litre—that may be legally required. Every publication must make its own choice as to whether it wishes to be scientific or legal.—I am, etc,

Investigation and Treatment of Delinquency

SIR—Dr Edward Glover opens his article (March 29, p 421) as follows "Looking back over the development of clinical psychology during the past quarter of a century it is now perfectly clear that our understanding of ego disorders has lagged woefully behind that of the neuroses and other varieties of 'encapsulated' symptom formation, using this term to convey that a given symptom does not infiltrate the normal layers of the patient's ego."

There must be many besides me who find this Freudian terminology difficult to comprehend, and I venture to doubt if it be essential for a proper understanding of the subject. The conscious functions of the brain are surely clearly divided into those of the intellect + reason and the emotions + propensities. In the genus *Homo* not only in its species *sapiens* but doubtless in the extinct *Cromagnon*, *Neanderthal*, and *Eoanthropus*, the emotions take precedence over the intellect in staggering percentage, otherwise the whole gamut of faiths, from animism upward would hardly hold the influence they do over the 2 000 million of the world's inhabitants.

Crimes are roughly divided into those, like murder, which if not suppressed would quickly bring about the end of civilization and are universally condemned the world over, and, on the other hand, acts which the political majority decry or consider to have harmful tendencies (varying of course from country to country). All these latter are dealt with by laws enforcing preventive methods or by the introduction of reformatory methods, placing on probation, or actual Borstal treatment. The line between alienation and crime is to a great extent artificial the former

supposing the subject to be irresponsible either by developed mental defect in the nervous system, or due to that in addition to a diseased state. In the latter the subject's nervous system is judged sufficiently normal for the subject to be regarded as responsible for the forbidden act. The above appears to define the essentials to be kept in mind in dealing with delinquency and carrying out the treatment thereof.

We know that in ancient times among the Egyptians and other priesthoods cryptic methods and writings were used in order to dominate their peoples and enforce them to conform to the laws enacted, but surely simple plain language is sufficient in the present century, without making use of these Freudian embellishments—I am, etc,

Hove Sussex

WM BRYCE ORME

SIR—Every psychologist will support Dr Edward Glover's appeal (March 29, p 421) for wider facilities for the scientific treatment of delinquency and for further research on "every variety of delinquent or pre-delinquent conduct." Yet many will regret that he endorses the view, so frequently repudiated by other psychiatrists, that delinquency is primarily a medical problem. His list of "the different types of delinquency—e.g., neurotic, psychotic, psychopathic, mentally defective organic, etc"—covers only about 10% of the numbers, the remainder, chiefly non-medical cases, he wholly disregards.

He regrets that "the authority of medical psychology" in this field has not as yet been fully recognized. But he himself supplies the explanation "Looking back over the development of clinical psychology during the past quarter of a century," he notes that the problems of delinquency have been "the last to stimulate the curiosity of the psychopathologist." Yet the educational psychologist started to investigate the subject more than 40 years ago, 10 years later the Education Committee of the LCC appointed a psychologist to deal with this and allied problems. In an early report it was stated that over 60% of the cases were successfully "cured," while another 20% showed "definite improvement." Dr Glover reports "striking results" in certain types of case. But he offers no figures.

When teachers, magistrates, education officials, and the like are asked why they doubt the authority of the medical psychologist, their answer is that his treatment so often fails, because it overlooks the type of cause with which they are all too familiar. The medical psychologist is apt to assume that the main cause of the delinquency lies within the delinquent himself, accordingly he either looks for and treats suspected physical and organic disorders, or thinks solely of "inner mental mechanisms," which he interprets in metaphors drawn from physical disease—as when Dr Glover describes delinquency as a variety of "encapsulated" symptom-formation, indicating that the symptoms do not infiltrate the normal layers of the ego. "Actually," he says, "we know more about the mechanisms of the psychoses than we do of the causes of crime." That may be correct, if "we" refers to psychopathologists, but a glance at the psychological literature will show that the causes are now well known. What calls for research is the efficacy of different treatments.

All will agree that such research requires "specially trained investigators." But the essential part of their training must consist in a study not merely of mental and nervous disorder but of individual and social psychology. At present, with one notable exception, this is not included in psychiatric courses. Yet the need is obvious. It is a plain corollary not only to the Home Office inquiries but to the investigations carried out by Dr East while Medical Inspector of H.M. Prisons. As he points out, crime can no longer be regarded as a disease. It is a problem of social adjustment rather than of mental abnormality, and the most successful mode of dealing with it lies, not in psychotherapeutic treatment, but in an intelligent adjustment of the delinquent's own environment and in a re-education of the delinquent himself in improved social conditions. A small minority of genuinely pathological cases will of course always remain, and for these the methods described by Dr Glover are both urgent and essential.—I am, etc,

University College London

CHARLOTTE BANKS

Vaginal Operations

SIR—Mr Wilfred Shaw must be congratulated upon his brilliant article on this subject in your issue of April 12 (p 477). The description of the anatomy of the vagina given in standard textbooks has long been considered inadequate by gynaecologists and Mr Shaw has filled this gap. It is pleasing to note that Mr Shaw has considered the vagina not only a passage for childbirth but from a broad point of view which embraces the important functions of micturition and coitus.

Gynaecologists have for many years concentrated upon plastic operations which, although eminently satisfactory in the cure of prolapse, have often resulted in producing a vagina which proved useless in coitus and did nothing to relieve the distressing symptoms of stress incontinence, it is to be hoped that Mr Shaw's article will do something towards altering this state of affairs.

Finally, I am very pleased to see that Mr Shaw advocates vaginal hysterectomy in certain cases of prolapse. This is an important step forward, since by this operation the prolapse is cured and the danger of subsequent carcinomatous changes occurring in the cervix removed. This is particularly important when one remembers that carcinoma of the vaginal portion of the cervix only occurs in women who have been pregnant and prolapse, although not unknown in nulliparous women, usually occurs in those who have had difficult or repeated pregnancies—I am, etc

Southport

JOHN H. HANNAN

Retrodisplaced Gravid Uterus

SIR—Mr H. H. Fouracre Barns has replied (April 12 p 504) to my letter regarding the above. I am unrepentant in the matter of my deduction in Mr Barns's patient No 39. I am sure that Mr Barns will share with me the experience of finding a uterus retroverted after a ventrosuspension operation has been carried out even in a "reputable London teaching hospital." This I believe to be due not to any failure on the part of any individual operator but to a defect of the method of ventrosuspension most commonly used—namely Gilliam's operation and its modifications—in that it fails adequately to "take up the slack" of that portion of the round ligament which lies in the canal of Nuck, and which may in some cases be extremely elastic. The round ligament is thus left free to slip back out of the canal into the abdomen and permit the uterus to resume a position of retrodisplacement. This is one of the reasons why a modification of the operation of ventrofixation has continued to be used in the Liverpool School by certain distinguished operators, although various other methods are commonly in use. The multiplicity of methods of ventrosuspension which have been advocated from time to time (Crossen describes 19 different procedures) proves that none is uniformly successful, and I hope therefore that my deduction in my previous letter will not arouse the indignation of those responsible for the ventro suspension operation in the patient in question. In any event my justification is in Mr Barns's own statement that in 1943, three years after operation she was seen with a retrodisplaced uterus.

All the above, however, is not germane to the point at issue, and while I should be the last to deny that conservative treatment may be successful in maintaining a normal position of the pregnant uterus and therefore in promoting the successful completion of a pregnancy, I submit that in some cases, such as my own case quoted in my previous letter, ventrosuspension is necessary to ensure that the pregnancy shall continue to term.

With regard to the fact of circulatory factors (I apologize to Mr Barns for attributing to him the opinions of Mr Barnett) I would suggest that these may operate so as to cause abnormal development of the ovum apart from any question of its nidation and that this ovular abnormality may be the cause of an abortion after a relatively long interval such as that in Mr Barns's case No 42. There again the effect upon any given ovum of a minor circulatory abnormality is liable to variation and some might escape abnormality entirely thus explaining the cases of incarceration which are not followed by abortion. In habitual abortion it is often very difficult to find the cause, but the condition is a source of considerable disappointment and

sorrow to the patient and to her husband and a cause of much unhappiness. In many cases I am forced to admit with Mr Barns that I do not know the cause of the abortion, but in those in which retrodisplacement is present I feel that it is wrong to deprive the patient of the improved chance of a successful pregnancy which I believe ventrosuspension can give her—I am, etc

J. A. CHALMERS

Post-partum Intra-abdominal Separation of Uterus

SIR—The following extract from our textbook, *A Glasgow Manual of Obstetrics* (by S. J. Cameron and John and Ellen D. Hewitt), may have a bearing on Dr J. J. S. Wassenaar's case of post-partum intra-abdominal separation of the uterus (April 5 p 452). We would warn the practitioner to carry out removal of the placenta with the greatest caution as, owing to the softened condition of the uterine tissues, the wall of the organ may readily give way before the advancing fingers, and a practitioner has actually removed the entire uterus from the tissues above the cervix in the belief that he was detaching the placenta. One of our most trustworthy house surgeons also had this unenviable experience, and he assured us that in accomplishing this unpremeditated hysterectomy he experienced less resistance from the tissues than he had in other cases of retained placenta—I am, etc,

Helshill Lanarkshire

SAMUEL J. CAMERON

Nicotinamide and Diabetes Mellitus

SIR—I was most interested in Dr Henry J. Wade's memorandum (March 29, p 414). The investigations he describes were similar to those which I conducted in 1943. Since then I have felt that in only a very small percentage of diabetics could treatment with nicotinic acid be of any value. To demonstrate the effect of nicotinic acid and/or nicotinic acid amide it is necessary to test its effect on normal subjects, with and without insulin. Both preliminary tests were done before my article was published (Neuwahl, 1943), but its full implications were not realized at that time. A typical curve of 2½ units of crystalline insulin plus 150 mg of nicotinic acid given at the same time, is given below. The subjects were on a standard diet, so that fasting blood sugars were about 85 mg per 100 ml.

Fasting blood sugar	85 mg per 100 ml
2½ units of insulin plus 150 mg of nicotinic acid	intramuscularly
Blood sugar 2 minutes later	95 mg per 100 ml
5	109
10	95
15	77
20	109
25	119
30	105
35	121
40	141
60	141
90	77

This typical reaction has in fact spoilt every attempt to classify diabetics as suitable or unsuitable for treatment with nicotinic acid. After testing more than 50 patients only a small group of five remained which were insensitive to insulin and at the same time had probably an abnormally weak glycotrophic pituitary factor. In these the action of endogenous insulin could be heightened when the action of nicotinic acid was carefully watched, and the dosage reduced as soon as results appeared satisfactory, to prevent the glycotrophic factor being stimulated. The latter appears to increase in direct proportion to the action of insulin. The anti insulin action is apparently exerted through the adrenal cortex, and the first stage of action seems to affect the adrenal medulla, which liberates adrenaline. Thus the action of the "reinforced insulin" becomes obscured by an accelerated breakdown of both liver and muscle glycogen. The surplus discharge of adrenaline may also explain the undoubtedly favourable effect of nicotinic acid in cases of asthma, which was commented upon by G. Melton (1943)—I am, etc,

Myiasis of Palpebral Conjunctiva

SIR—The following record of a case of myiasis of the palpebral conjunctiva is of interest

CASE REPORT

A negro oilfield metal turner aged 32 presented himself at the dispensary, saying that a piece of cast iron had got in his right eye in the course of his work that day. He complained of the usual irritation, but there was no infection of the cornea. After a search a minute foreign body was removed from the upper palpebral conjunctiva. The eye was washed out with boric lotion and he returned to work. Two days later he returned saying he still felt something in his eye.

On examination the conjunctiva was slightly infected and there was a small area of inflammation in the centre of the upper palpebral conjunctiva. As this appeared to be a focus of sepsis following removal of the foreign body, hot spoonings and irrigations with boric lotion were prescribed. A week later the man was seen again. There was a large swelling below the upper lid, which raised the lid off the eye, and he complained of frequent attacks of severe pain and inability to sleep for several nights.

The appearance was that of a large styte pointing on the underside of the eye, so 4% cocaine was instilled preparatory to incising it. When the lid was everted as much as possible there appeared to be two openings, and owing to the pressure a white object could just be seen in one of these openings. Increased pressure disclosed more of this object, and it was seen to be segmented with a row of bristles between each segment. Slowly a large larva of *Cordylobia anthropophaga* (tumbu fly) was extruded from the swelling, greatly to the amazement of all present. The larva was 3/4 in (1.9 cm) long and as thick as a cigarette. The patient was immediately relieved of his symptoms, and within two days the eye was to all appearances normal.

Infestation of various fleshy parts of the body is commonly seen, but this is the only case I have heard of in which it occurred in the orbital cavity—I am, etc.,

Santa Flora, Trinidad

T E M WARDILL

The Label of Psychoneurosis

SIR—During the last year I have been able to survey a large number of persons invalided from the Services with psychoneurosis. A great number of them complain bitterly that the label prevents them obtaining suitable employment. It is becoming evident that many employers, without proper consideration, look upon them as defective in character and mentality and as unfit for steady employment.

To my mind from an employment point of view there are two classes of psychoneurotics. (1) Those with a history of neurosis from childhood with a bad occupational record and who rapidly became useless in the Service because of black-outs, headache, apathy, and general poor morale. The employers quite rightly are rather chary of taking them on, for they cannot be relied upon to continue at steady work. Incidentally, I estimate not less than 15% of the total population belong to this class of ineffective unemployables, and it is they who ruin the harmonious working of many social services. (2) Those with a good employment record, who have done a fair amount of service but have eventually broken down under stress the severity of which they are unlikely to encounter in civil life. It is these men who suffer so unjustly from the label of psychoneurosis. Sometimes they have done over five years service or been through the Battle of Alamein or Salerno, or Caen or been on submarine service or completed 20 operational tours over Germany. Given a chance and a considerate employer they regain their confidence and return to normal—though they can never lose the stigma of psychoneurosis.

Solely on behalf of this latter group I would like to suggest (a) That invaliding medical boards when considering a man who has served his country well avoid the term psychoneurosis, and prefer terms such as battle exhaustion, tropical debility, flying stress etc. (b) That employers look more fully into a man's war service and the stress he has sustained before classifying him as a constitutional psychoneurotic.

Until laymen appreciate the difference between the above groups some very good men will continue to resent the label of psychoneurosis, and it is to bring this matter to light that I am writing this letter—I am, etc.,

London W 1

KENNETH HAZELL

Quinine and a Resistance Factor

SIR—I read with interest Dr E O Blake's letter (April 12, p 506) on the treatment of early cases of influenza and the common cold by the intravenous administration of quinine bi-hydrochloride. In fact the use of small doses of quinine by mouth by laymen in many countries to abort such attacks has stood the test of time. At first sight such a procedure seems quite irrational in view of the accepted idea that quinine is a drug with specific antimalarial action. But is it so?

It is generally held that quinine *in vitro* is ineffective unless large concentrations are used which are not tolerated by macrophages. This immediately suggests an indirect mode of action. Recently Black (*Trans Roy Soc Trop Med Hyg* 1946, 40 163) reported that serum from a patient treated with quinine arrested the development of trophozoites of *Plasmodium falciparum* when cultured *in vitro*. He had excluded the specific immune properties of sera used in the culture as an influence detrimental to the parasite since the parasites were taken from patients with a primary attack while the drugs were given to donors who had not had falciparum malaria. He had also excluded phagocytosis, since leucocytes were removed before cultivation was begun. This suggests that this indirect mode of action is humoral and non-specific. Of great interest is his finding that most of the parasites undergo schizogony in a control culture, using serum from healthy donors containing no drug, and that the second generation does not progress so readily. He comments that this method of cultivation does not provide ideal conditions for the development of the parasites. But why should serum from normal volunteers offer a handicap for the growth of these parasites?

At the last laboratory meeting of the Royal Society of Tropical Medicine I demonstrated the mechanism of action of two antimalarial drugs studied—quinine and atabrin—with reference to a new resistance factor found in the albumin residue and revealed by the serial cephalin flocculation curves. This resistance factor proved to be of great significance in determining the course and outcome of this struggle between host and parasite. A decrease in this resistance factor shifts the balance in favour of the parasite and when marked is associated with clinical manifestations of disease, while an increase in this resistance factor shifts the balance in favour of the host tending to re-establish a condition of health. This latter effect is obtained by the administration of quinine to healthy volunteers as well as to malarial patients, thus explaining its non-specific and indirect mode of action as an antimalarial and possibly also as an antiviral and antibacterial agent. Since this resistance factor is also present in healthy persons to a less extent than in healthy persons treated with quinine it is apparent why normal serum should offer a handicap to the growth of *P. falciparum* when cultured *in vitro*. A more detailed account is in the press—I am, etc.

London W 2

J G MAKARI

d-Tubocurarine in Caesarean Section

SIR—I was most interested to read Dr T Cecil Gray's excellent article on this subject (April 5 p 444) particularly as the choice of anaesthetic for caesarean section is such a controversial matter. The questions that seem to arise are (1) If the combination 'kermithal-cyclopropane-oxygen' is to be used, is it necessary to use *d*-tubocurarine at all? (2) If *d*-tubocurarine is used, do the advantages obtained definitely override the possible dangers attendant upon its use?

It seems that using cyclopropane-oxygen alone on the closed circuit, adequate anaesthesia can be obtained for caesarean section without using harmful doses of the anaesthetic agent. Little relaxation is required and the babies seldom cause anxiety. Anaesthesia is usually light and after delivery, not below deep plane one or upper plane two of the third stage. The patients in the great majority of cases recover their reflexes in the theatre. Post-operatively their condition is satisfactory and vomiting not a regular feature. True intubation is no doubt facilitated if it should become necessary and uterine tone good if *d*-tubocurarine is used with the above combination, but as Dr Gray reports this latter fact caused a temporary embarrassment to the surgeon on two occasions.

If *d* tubocurarine is to be used as an aid to anaesthesia for caesarean section its powers would perhaps be even more fully appreciated if combined with kemithal-gas and oxygen provided suboxygenation did not occur, for here the unpremedicated patient strains and resists anaesthesia is more liable to vomit during induction and usually requires the addition of trilene or ether.

In the future as reports come in perhaps all parties will be satisfied and the advantages of Dr Gray's method obtained with myanesin in combination with general anaesthesia, but with a wider margin of safety and no respiratory depression.

There seems a tendency at present for anaesthetists to use *d* tubocurarine indiscriminately as the solution to all their problems in the hands of one as experienced as Dr Gray it can only be an advantage but no one will deny that in the hands of the occasional anaesthetist its potential dangers may become real—I am, etc.,

Cambridge.

ROBERT I W BALLANTINE

Child Guidance

SIR—Dr J. A. McCluskie's letter (April 12, p. 508) illustrates the unnecessary confusion that there is on this subject. I suspect that, like many current misunderstandings it is largely due to people failing to read or comprehend the documents that they criticize. Since he refers—although not by its correct title—to a recent memorandum produced by a subcommittee of which I happen to be the convener I should be glad of an opportunity to correct the misleading impression that may result from his interpretation of the subcommittee's views although I do so as an individual. The subcommittee is part of the Medical Advisory Committee of the Berks Bucks, and Oxon Regional Hospitals Council, not that of the Nuffield Trust although it was set up by virtue of the activities of the latter body, and the memorandum refers to psychological medical services in the Oxford region only. It is appended to the council's report on the planning of hospital services in that region (January 1947). Dr McCluskie implies—para (c)—that the subcommittee advocate double administration clinics. On the contrary, this is the very thing that they deprecate. What they advocate is an arrangement very similar to that which Dr McCluskie describes and so obscurely calls 'the dual scheme under one administration'. Why introduce an element of contentiousness where none exists?

Most of the authorities that he quotes—and one notable one that he omits, namely, the joint memorandum of the R.C.P., the B.M.A., and the R.M.P.A. (Supplement 1945, I 111)—are agreed that the psychiatrist, with his essential technical assistants in psychometry and sociology, is the man to deal with mental illness and defect in children, and that it were better that this team should be integral with the health services, although they will probably do some of their work in *ad hoc* school clinics and some in the psychiatric department of a general hospital or in a special hospital. Thus they can deal with any patient in the place that is best suited to his needs, whatever may have been the point of first contact. It would ease relationships with education authorities if the distinction were more clearly recognized between an educational psychologist with a university training and degree in his subject on the one hand, and the more humble psychometrist, or mental tester, on the other, the latter may be an auxiliary technician in the psychiatrist's team or in the educational psychologist's department. But no realist would deny the educational psychologist his place in his own right, within the framework of the educational service for most of his work is far closer to education than it is to medicine. Psychiatrists, having rightly objected to a tendency, here and there, in the early days of this work, on the part of lay psychologists to undertake often in ignorance the treatment of an ill child should take care that they do not themselves commit a similar kind of offence by encroaching too far into the territory of the professional educationist.

At some points in some cases the two fields will overlap, symptoms may be scholastic, treatment medical, or vice versa. In the children's interests therefore, the administration system, however designated must be such as to provide smooth continuity from provisional diagnosis to investigation, to final diagnosis to treatment, no matter in what field symptoms arise, no matter through what channel help is sought (teacher and school M.O., or parent and family doctor, or juvenile court and probation officer) and no matter whether the prepotent therapeutic factor lies in the tutorial skill of the educational psychologist, in the clinical techniques of the psychiatrist or the paediatrician, or in the activities of the social worker. The

only way to achieve this is to have an easily worked interconsultative arrangement of people who know their jobs and their limitations and who, while remaining masters in their own houses, have a pretty sound conception of the relevance of the other man's work and are big enough to refer appropriate cases to him and let him get on with his own job in his own way.

I should like to dispel the doubts that Dr McCluskie has about the subcommittee's experience of psychiatric disorders in children. All of its members have done a considerable amount of work in this field, and among them are two former and one present director of psychiatric clinics for children. The latter is actively engaged in the work of clinics—managed on lines similar to those advocated—in a predominantly rural county. This work has been going on for five years and it has not yet broken down as a result of geographical considerations in the way that Dr McCluskie so confidently predicts—he must be very far indeed ahead of the planners.

I hope that controversy on this subject will not be rekindled. The great majority of the authorities that have given it consideration and are versed in its practice are agreed on the fundamental principles, clearly their detailed implementations must be moulded by the peculiarities of diversely circumstanced localities, can't we leave the matter there?

And if I may be allowed a personal tail piece—can't we stop, once and for all, using this ridiculous expression "child psychiatrist"? If the words bear their correct meaning they suggest a bespectacled prodigy in a school cap rushing hither and thither to treat disordered patients. Who ever heard of a 'child surgeon', a "child ophthalmologist, or a child dentist"? Must we always be different?—I am, etc.,

Aylesbury Bucks.

IAN SKOTTOVE.

Medical Ration Book

SIR—The size of the medical profession, its geographical distribution, and the proportion of its parts are not fortuitous things, but have arisen, rightly or wrongly in response not to needs in a general way but to "effective demand" in the special economic sense. The first result of making all demand effective by taking medicine out of the market will therefore be similar to that observed with other commodities in short supply—namely there will not be enough to go round. The number of medical items of service necessary to ensure theoretical perfection in practice (and to avoid future questions in Parliament) is limitless and therefore until the majority of the brains of the country can be mobilized and applied to the problem of keeping healthy people well and making sick people more introspective, some form of rationing will have to be devised.

It would appear that the simplest and fairest system, and one which is already familiar and highly esteemed would be some form of medical ration book. With the assistance of officials from the B.O.T. and the M.O.F. an estimate should be made from the supply side (there would obviously be no point in estimating demand as the limiting factor is supply) of the number of items of medical service available from year to year, and these should be divided up among the total population with special weighting for infants and the aged. A number of general coupons would be provided in the book and also pages of coupons for the various specialties: hospital beds, surgical operations, drugs, and appliances. On each page could contain photograph, finger-prints, blood pressure, identity number, height, weight, chest expansion, size of collar and shoes, blood-type, number of moles on the body, and other information likely to be helpful in diagnosis.

The patient would register with a general practitioner for the basic ration as it were but the specialist coupons could be used freely (like 'personal points') as taste or necessity indicated. As the total available services had been accurately estimated, there would be no need to insist that coupons should be non-transferable though the possibility of a 'black market' developing among hypochondriacs might require certain restrictive measures. The healthier members of the community could hand in coupons which they were not likely to require during the current period of say six months to a central pool controlled by a panel of consultants so that there would be no shortage of say, 'barbiturate coupons' for patients consulting psychiatrists or of "dental coupons" for orthopaedic—

patients. The validity of coupons would, of course, have to be confined to the area in which they were issued in order to avoid excessive travelling to Harley Street in search of health, though possibly the nationalization of transport would itself in time prevent people from leaving their birth place without adequate reason. However, a few starred coupons could be included in each book to allow of consultations with titled specialists. Extra coupons could easily be included for those in occupations having a high sickness rate. Leucotomy coupons could be provided for those engaged in economic planning, and euthanasia coupons for those who, owing to possible visual field defects, can see no future to the left of the left.

The whole scheme has the great merit of being simple and easily understood. Book-keeping would be reduced to a minimum, the cost of the service would be known in advance and could not be exceeded and all the doctors and consultants would have to do would be to cut out the coupons and affix them to a gummed sheet. Each full sheet would then represent a certain sum of money which could be either immediately passed for payment or transferred to the Inland Revenue Department as an income tax credit—I am, etc.

Bournemouth.

T R AYNLEY

The Plebiscite

SIR—I have noted of late with considerable misgiving, the lack of stimulating correspondence in your columns on the proposed National Health Service.

Between Nov 16 and 23 last year all members of the medical profession received a voting form for the plebiscite which was to ascertain how many of us were willing for the Negotiating Committee to enter into negotiations with the Minister of Health on the new Health Service. The final results as published in your issue of Jan 11 (p 64) showed that 46% voted for and 54% voted against negotiation. A clear majority of 8% against negotiation. Two weeks later, however, in the *Supplement* of Jan 25 (p 9) we were told that 'the Association, having considered the final results of the plebiscite and the Minister's letter of Jan 6 to the Presidents of the Royal Colleges, is willing that discussions be entered into with the Minister'.

It is an axiom of the supporters of the present Government that the Socialist Party has a clear mandate from the people to establish a national health service. I have taken the trouble to obtain the voting figures for the last General Election. The Socialists polled 48%, the Conservatives 36%, and all other parties 16% of the total of 25 million votes.

The Socialist Government therefore represents the wishes of less than half the population that voted. Yet a clear majority of 8% of doctors was considered an insufficient number against negotiation.

It is time that medical men and women shook off the apathy consequent upon six years of war and two years of peacetime controls and restrictions and realized that unless we stand firmly together and refuse to co-operate in Mr Bevan's health service we shall awake one day to find ourselves bound in the bonds of a National Socialist State where the right to question the opinions of those in authority is a crime punishable by professional if not physical, death—I am, etc.

Bromley Kent

MICHAEL B CARSON

The Chartered Society of Physiotherapy

SIR—I should be grateful if you would bring to the notice of the medical profession the correct title of the members of the Chartered Society of Physiotherapy. Until 1943 our Society was known as the Chartered Society of Massage and Medical Gymnastics. The new title is a more comprehensive one and the correct designation for a member is that of 'chartered physiotherapist' or M.C.S.P.

The members of the Chartered Society of Physiotherapy have always welcomed the opportunity of close co-operation with the medical profession and patients are only accepted for treatment when referred by a doctor—I am, etc.

London, W.C.1.

W S C. COPEMAN
Chairman of Council

POINTS FROM LETTERS

Loose Spectacle Lenses

Mr J G H COOPER (Portsmouth) writes: I hope that you may be willing to give a small part of your space to a subject which may help children who, like my own, wear glasses to correct a squint. In the course of their use these glasses invariably become loose, consequently when cleaning the lenses they are sometimes rotated. If this happens, so the optician tells me, the squint far from being cured will be made worse. This is so in nearly every case of glasses prescribed for squints, which are usually circular. Therefore the glasses must be returned for resetting every time it is suspected that the lenses have moved. This could be obviated by a locating peg in the frame and a notch in the edge of the lens.

"Are they, Mum?"

Dr A R STUART WARDEN (Brighton) writes: I recently had occasion to ask a young woman aged about 18 whether her bowels were regular. She turned to her mother and said, "Are they, Mum?" It seems to me that these three words completely sum up the modern system of State education. Volumes could say no more.

Volvulus of the Caecum

Dr G C PETHER (Colchester) writes: Mr R H Gardiner's article (Jan 18, p 83) interested me since I reviewed much of the literature on volvulus of the caecum some years ago. The dietetic factor, which he mentions, is one commonly met in the Balkans and certain Slavonic and other countries of Eastern Europe. In some of these it is customary to take only one meal a day, and, as may be imagined it is a big meal. Furthermore it contains a large amount of roughage of vegetable origin, and apparently the accumulation of this large mass in the caecum causes both sagging and distension. If I remember rightly the literature from the countries mentioned also refers to the high incidence about the seventh month of pregnancy. Presumably, since the British diet is so different, the percentage incidence in this country is much lower.

Control of Measles

Mr H ELWIN HARRIS FRCS (Bristol), writes: Dr A Crawford Mayer's letter (April 5, p 475) calls for little comment. Controls are not possible in private practice, but during a measles epidemic some years ago, which was characterized by a very virulent type of otitis media, none of the oiled patients had any complications. As a result of my previous letter (March 8, p 323) I received a letter from an ex nurse, who wrote that she "worked with a doctor at the Victoria Hospital, Stepney, on the treatment of scarlet fever and other infectious troubles by the use of eucalyptus oil and carbolic oil, with very marked success, and had the doctor lived I think the treatment would have been far more widely known than it is at present. I may say that in the four years I was working at the hospital we had only one case of infection, even though we nursed all cases in general wards and took no precaution with laundry."

Price of Vitamin B₁

Dr MAURICE JOWETT (Glasgow) writes: Vitamin B₁ is being made in the United States for 16 cents, or say 10d, a gramme (R R Williams, *Chem Ind* 1947 66 123). At this rate a bottle of a hundred 3 mg tablets which is sold to the public in this country at a price of 9s, contains three-pennyworth of the vitamin.

Fuel Abstracts a monthly summary compiled by the Fuel Research Station of the Department of Scientific and Industrial Research, is available to the general public from January, 1947. The summary comprises more than 500 abstracts a month of the world literature on all technical and scientific aspects of fuel and power. It is published by H M Stationery Office, Kingsway, London, W.C.2. During 1946 more than 6,400 abstracts were provided. Each monthly issue includes a subject index, and every six months complete author and subject indexes are issued. The summary is printed on both sides of the paper. The subscription for this service, now for the first time made generally available to technical, scientific, and commercial bodies, and to individuals is £2 10s per annum, covering 12 monthly issues and two half-yearly indexes post free. The charge is sufficient to cover the cost of printing and postage alone. Individual copies will not be for sale separately. Back numbers prior to Jan 1 are not available.

Obituary

HAROLD MOODY, M D

Dr Harold Moody, who died in London on April 24 at the age of 64 was the founder and president of the League of Coloured Peoples. He was also the first negro chairman of the London Missionary Society and the first negro president of the British Christian Endeavour Union.

Harold Arundel Moody was born at Kingston, Jamaica, in 1882 and he came to this country in 1904. A student of King's College Hospital, he won the Barry Prize in 1906 and the Tanner Prize in obstetrics and the Todd Medal in 1910. He took the Conjoint Diploma in 1911, the M B, B S a year later, and proceeded M D in 1919. Soon after qualifying he acted as medical superintendent of the Marylebone Medical Mission, and he was also for a time senior clinical assistant in the out-patients department at King's. He built up a large practice in Peckham and at the same time took an active part in the work of the London Missionary Society. Only two years ago he became chairman of its African committee. He was also an active congregationalist and his house soon became a meeting-place for young West Indians, and later for other coloured students.

In 1931 Dr Moody founded the League of Coloured Peoples. To this body he devoted all the time he could spare from a busy general practice. It was only recently that he handed over to others the day to day business of the League which he had previously conducted himself with remarkable perseverance and tact. Not long ago he visited the West Indies, where his brother, also a doctor, is in practice, in connexion with a new scheme to set up a communal centre for coloured people in South London. Dr Moody had been a member of the British Medical Association for over thirty years. He was also on the council of the Save the Children Fund, and as vice-chairman of its Child Protection Committee he took a special interest in the establishment of a pioneer maternity and infant welfare centre in Nigeria.

Dr Moody was a deeply religious man, and he achieved substantial success in his declared aim of showing by his way of life and by the force of example that colour was professionally and socially irrelevant. A familiar figure in the Colonial Office and other Government Departments, Dr Moody won the respect and admiration of all those with whom he came in contact. He is survived by a widow and six children, of whom two are members of the profession.

G HARRISON ORTON, M D

Dr George Harrison Orton, one of the pioneers of radiology, died on April 18 in St Mary's Hospital, at the age of 74. The eldest son of the late George Hunt Orton, F R C S, he was educated at Charterhouse School, Trinity College, Cambridge, and St Bartholomew's Hospital. He took the M A, the M B, B Ch and the Conjoint Diploma in 1901 and proceeded M D in 1906. Even before 1906 he was writing on the value of radiology in the diagnosis of diseases of the chest, and thirty years later he contributed an article to the *British Journal of Radiology* on the importance of calcium changes in diagnostic radiology. Other papers from his pen were on the diagnosis of renal and ureteric calculi, and he was also responsible for several articles on x-ray therapy. Dr Orton was successively radiologist to the King George V Military Hospital, medical officer in charge of the x-ray and electrical department of the Royal Free Hospital, and chief assistant in the x-ray department at Barts. For many years he had been consulting radiologist to St Mary's Hospital, to the Graylingwell Military Hospital at Chichester, and to the National Hospital for Diseases of the Heart.

In 1913 he was secretary of the section of radiology at the seventeenth International Congress of Medicine which was held in London in that year. He was a member of the council of the Medical Society of London and a former president of the electrotherapeutic section of the Royal Society of Medicine. Dr Orton acted as secretary of the section of electrotherapeutics

and radiology at the Annual Meeting of the B M A in 1911, and he was president of the section of radiology at the 1933 meeting. He was also joint secretary of the British X-ray and Radium Protection Commission and was an examiner in radiology for Cambridge University. In his earlier days he was associated with the Cheyne Hospital for Sick Children and Mount Vernon Hospital. Like others who were interested in radiology before all its dangers were fully realized, Dr Orton paid a heavy price for the contributions he made to its development. His long sufferings were patiently borne and he had the satisfaction of seeing the subject to which he contributed so much become a full-grown specialty.

Dr CHARLES JAMES BOUCHER died at his home in Bangor Co. Down, on March 16 at the age of 70. A student of Queen's College Belfast, Dr Boucher qualified in 1903. Not long afterwards he was serving as a surgeon commander in China and in other parts of the Far East. In 1909 he settled in Donaghcloney where he built up a large general practice. He had been a member of the British Medical Association since 1905, and was chairman of the Portadown and West Down Division in 1922 and honorary secretary of the division for over ten years. He was also president of the Banbridge Practitioners' Club. Apart from his professional interests, he served the British Legion as vice-president of the local branch, and he played cricket and golf, and was a keen angler. On his retirement from active practice, because of failing health, he took a house in Ballyholme, Bangor, and he had been there for a few months before his death. He is survived by his wife, a daughter, and a son who is in the profession.

Dr JAMES LIVINGSTON MORTON died in London on March 21 at the age of 47. Inheriting considerable wealth at an early age, Morton travelled extensively and did not start his medical studies at Queen's University Belfast, until he was in the late twenties. He qualified in 1934, and was a colourful and popular figure. He had been in practice at Surbiton and later at Coulsdon.

A colleague writes: I knew Morton as a student with an amazing gift for languages and caricature drawing together with an equally remarkable ability to size people up. His generosity was lavish and several students who fell upon hard times were enabled to continue their studies through his benevolence. Morton practised first at Surbiton and later at Coulsdon, where he died. He was very successful in both practices and very popular with all who knew him, but his heart was in Northern Ireland where he spent his youth and few persons were so well known and well liked there. Hundred of Ulstermen will miss him and mourn his loss.

Dr HORACE CHARLES COLYER died at his home in Croydon on March 26 aged 63 years. Born at Ryde in the Isle of Wight in 1884, the son of a dental surgeon, he decided to follow his father's profession and entered the Royal Dental Hospital, where he took his L D S in 1905. He obtained his conjoint diploma in 1907 at University College Hospital. Returning to the Royal Dental Hospital he became house surgeon and later demonstrator after which in 1910 he settled in Guildford in dental practice. In 1914 he joined the R A M C as one of the original six dental surgeons posted to a C C S at Hazebruck. Later he transferred to medical duties and was attached to the R F C. In 1917 he was gassed and this seriously affected his health and career. After the war Charles Colyer soon realized that as a result of the damage to his sight by mustard gas he would be unable to continue as a dental surgeon. His interest in dental radiology had taken up the career of radiologist and after studying at Liverpool he began to practise in Croydon. He held appointments as radiologist to the Purley and District War Memorial Hospital, to Princess Elizabeth's Hospital, to the Mayday Hospital, Croydon and to All Saints' Hospital. In 1937 he published an article on tomography a branch of his work to which he was much interested. The apparatus he used was largely constructed by himself, he had considerable mechanical ingenuity combined with manual dexterity. Early in the recent war a land mine destroyed his house and consulting room, luckily without injury to himself. Some of his apparatus was saved and he was able to form a partnership with a colleague who was similarly placed and continued in practice until last year, when owing to increasing disability, he retired. Charles Colyer had been a member of the British Medical Association for many years. His straightforward and simple character endeared him to all with whom he came in contact and much sympathy will be felt by his friends for his widow.

Dr JOHN STEVENSON MITCHELL, of Bridge of Allan, Stirling-shire died suddenly on April 4 at the age of 65. Dr Mitchell was a student of Edinburgh University. He qualified in 1905 and took the FRCS in 1909. After a period as house-surgeon and house physician at the Edinburgh Royal Infirmary, Dr Mitchell acted as assistant to Dr Henderson of Galashiels. He took up practice in Bridge of Allan in 1912. During the first world war he served with the RAMC in the Middle East. When he was demobilized he returned to his practice and entered into partnership with Dr Welsh. In the recent war Dr Mitchell acted as medical officer of the Stanley House Auxiliary Hospital, and he continued his work as a lecturer and examiner for the Red Cross. He had always led a busy professional life and he died only a few hours after completing his usual day's work.

Dr WILFRID BOOTHBY BLANDY of Nottingham, died at the age of 68 on April 1. Dr Blandy took the LDS RCS in 1900 and the MRCS, LRCP in 1902. He was a house-surgeon at Charing Cross Hospital, where he had received his medical training and for many years he practised in Nottingham. He served in the Middle East with the RAMC from 1917 to 1919 and soon after his return to Nottingham he was elected to the local council as a member for Meadows Ward. He was president of the Nottingham Medical Society in 1938, and he had a great deal to do with the establishment of the new sanatorium at Newstead. One of his principal interests was work in connexion with the Nottingham branch of the British Red Cross Society, of which he became county director. He was also a member of the University College Council and had been chairman of the Board of Governors of the Nottingham High School. Dr Blandy, whose death will be regretted by all who knew him in the Nottingham area, is survived by his widow and two sons.

Dr FRITZ WEIGERT director of the physico chemical department of the research institute at Mount Vernon Hospital, died on April 13. Born in 1876, Fritz Weigert during his seventy years of life achieved much. Appointed to Nernst's Institute in Berlin in 1905 he went on to Berlin University as lecturer in chemistry in 1908. In 1914 he was appointed professor of scientific photography and photochemistry at Leipzig. From then on there came a continuous flow of research papers ranging over the fields of physical chemistry, photochemistry, and photographic methods applied to chemistry. During this period also he wrote a number of books, in particular the well known *Optische Methoden der Chemie*. In 1936 he came to England and at an age when most men would willingly have retired, Fritz Weigert started life anew. With the enthusiasm and energy that were so typical of the man he threw himself into the task of building a new career in a new country. Whilst holding a fellowship at Glasgow University he continued his research work. Then in 1939 came the change to an entirely new field. Applying his favoured optical methods he worked at Mount Vernon Hospital, Northwood, and was soon responsible for a series of papers adding to our knowledge of the metabolism of the chemical carcinogens. He was working at this problem right up to the day of his death. Away from the scientific work which was the mainspring of his life Fritz Weigert was a charming and cultured host and companion. Despite almost total deafness an argument was entered into with zest and enlivened by many a witicism and penetrating comment. The loss of this versatile scientist whose enthusiasm and energy never flagged is deeply regretted by a host of friends, whose sympathy is extended to his widow and two children.—G C

The Services

Captain (now Temporary Lieutenant Colonel) P C Mitchell M.C., has been awarded the Efficiency Medal (Territorial).

DEATHS IN THE SERVICES

Lieut.-Col CHARLES AIKMAN GOURLAY D.S.O., died at his home at Carbridge, Inverness-shire, on April 5 at the age of 69. A student of the University of Glasgow he qualified M.B., Ch.B., in 1900, proceeding M.D. in 1912. Col Gourlay joined the IMS after serving at Netley Military Hospital. He spent many years in India and was for some time attached to a Gurkha unit. He served in Mesopotamia during the first world war, and he retired in 1924. On his return to this country he lived at Aberfoyle and in 1928 became physician superintendent of Erskine Hospital, which post he retained for twelve years. During the second world war he was a liaison officer with the Ministry of Health.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Titles of degrees of M.A., M.B., B.Chir. were conferred by diploma on Mrs E. W. Higgins in March.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC TRINITY COLLEGE

Lord Horder delivered the inaugural Frederick Price Lecture on "The Place of Nutrition in Social Medicine" in Dixon Hall, Trinity College, on May 1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council of the College held on April 10, with Sir Alfred Webb-Johnson, Bt., President, in the chair, Dr S. S. Beare and Dr E. H. R. Altounyan were elected Fellows of the College, being Members of over twenty years standing. A Diploma of Fellowship was granted to P. D. Trevor-Roper.

The Begley Prize was awarded to Mr Ronald Charles Jordan, of Cardiff.

Prof W. E. Gye, F.R.S., and Dr James Craigie, F.R.S., were appointed Imperial Cancer Research Fund Lecturers for 1947.

It was decided to hold an additional Primary examination for the Fellowship in July.

The subject for the Jacksonian Prize for 1948 is "Malignant Disease of the Thyroid Gland".

The category of those entitled to attend the College monthly dinners was widened so as to include Fellows (when elected) and Licentates in Dental Surgery, holders of any of the specialist post-graduate diplomas, and all postgraduate students of the College together with their wives and guests.

The following hospitals were recognized in respect of the posts mentioned, the tenure of which is required of candidates for the Final Fellowship examination: Demerdash Hospital, Egypt (House surgeon and Resident Officer), Paddington Hospital (Assistant Medical Officer), Royal Buckinghamshire Hospital, Aylesbury (Senior House surgeon and Supernumerary House-surgeon).

Diplomas in Tropical Medicine and Hygiene and in Child Health were granted, jointly with the Royal College of Physicians of London to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE—H. E. Al Abed, H. Annamunthodo, D. W. Bell, R. H. Bell, J. S. Calnan, M. V. Chan, F. G. Domangue, A. El S. Eissa, H. S. Fuller, V. V. Gharpure, D. J. Gilbert, J. Harper, L. Jacobson, V. N. Jai, S. K. Kaan, E. Kertész, R. R. Lam, J. I. Lesh, K. H. Lim, J. P. Mackey, R. D. Maclean, R. C. Macleod, G. Y. Nan, M. G. Nelson, Y. H. Ng, Q. Pasha, S. H. Patel, I. B. Patwari, A. Qattan, R. V. Rele, S. C. Sanghani, A. O. Sasegbon, K. S. Seal, I. H. Syed, W. J. U. Tin, J. M. Vazley, A. J. N. Warack, Dorothy W. Wells, J. P. F. Whelan.

DIPLOMA IN CHILD HEALTH—Esmé Abelheim, J. M. Alexander, R. Asquith, J. N. Berry, D. W. Beynon, D. M. Brierley, Margaret Brodigan, J. Brody, J. C. Brown, R. W. W. Brown, Janet Cameron, W. A. B. Campbell, F. S. Carter, R. H. Caughey, Roma N. Chamberlain, N. A. Daniel, H. H. Davies, H. L. Ellis, Edith M. Evans, C. G. Fagg, D. M. Foubister, Elsie C. Gibbons, Mildred C. Green, Joan Guy, H. Habib, N. Hamlin, Margaret A. Hay, Frances A. Hepburn, J. B. Heycock, Patricia E. Hingle, A. Holzel, J. N. Horne, Margaret E. Hughes, J. Jacobs, A. P. Kalra, Nora Kelly, Doreen M. King, P. Kuschik, J. H. Lawrence, Joan M. Levell, M. E. MacGregor, Runa B. Mackay, G. F. Maggioni, S. L. Malhotra, N. M. Mann, Betty M. Margetts, P. Maurice, Lilian Morris, P. D. Moss, E. L. Murphy, A. P. Norman, W. H. Opie, A. Palley, A. N. Pearson, V. R. Pickles, B. W. Powell, P. M. M. Pritchard, E. P. Quibell, Joan M. Redshaw, Attracta G. Rewcastle, F. Rousseau, G. R. Royston, A. Russell, Isabel S. Smellie, Marion E. Smith, Ankele M. P. Snow, Margaret H. Stanfield, J. H. Steeds, Eluned M. Steven, J. K. Steward, Marian E. Sturrock, Laura Thompson, J. P. M. Tizard, I. P. Todd, A. B. Tompkins, Vivien V. Tracey, G. B. R. Walkey, Pauline H. Webb, R. C. Webster, R. H. White, Jones, Llyr, M. Williams, D. A. J. Williamson.

The following lectures will be delivered at the College (Lincoln's Inn Fields, W.C.) May 8, 5 p.m. Hunterian Lecture by Prof J. B. Macalpine, "Bladder Growths, with Special Reference to Growths occurring in Workers in Aniline Dyes." May 14, 5 p.m. Arris and Gale Lecture by Prof F. Wood Jones, "The Hall marks of Humanity." May 15, 5 p.m., Hunterian Lecture by Prof Rodney Smith, "Intestinal Decompression in the Treatment of Acute Obstructions." May 22, 5 p.m., Arris and Gale Lecture by Prof Lambert Rogers, "Ligature of Arteries with particular reference to Carotid Occlusion and the Circle of Willis." May 29, 3.45 p.m., Erasmus Wilson Demonstration by Mr L. W. Proger, "Pathological Specimens in the Museum." The lectures are open to those attending courses in the College and also to all other medical practitioners and advanced students.

A course of 72 Lectures in Anatomy, Applied Physiology, and Pathology will be given at the College from July 1 to 31 and from Sept 1 to 30 on Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays at 3.45 p.m. and 5 p.m. The fee for the whole course is £16 16s. Fellows and Members of the College and Licentates in Dental Surgery will be admitted on payment of £12 12s. It will not be permissible to take one or two subjects only. Applications, accompanied by a cheque for £16 16s. or £12 12s., should be sent to the assistant secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2.

TEMPORARY TREATMENT AND DIVORCE

[FROM OUR MEDICO LEGAL CORRESPONDENT]

Divorce for insanity, introduced by the Matrimonial Causes Act (Herbert's Act¹), 1937, was a complete innovation, and the provisions governing it were drawn very carefully and are interpreted very strictly. In the result several anomalies have come to light which inflict undue hardship on petitioners whose cases happen to fall just outside the boundary line. Under Section 2 (d) a petition for divorce may be presented on the ground that the respondent is incurably of unsound mind and has been continuously under care and treatment for at least five years. The words 'care and treatment' are precisely but somewhat narrowly defined. Section 3 says that a person of unsound mind is under care and treatment while (*inter alia*) he is detained in pursuance of any order or inquisition under the Lunacy and Mental Treatment Acts, or while he is receiving treatment as a voluntary patient, if such treatment follows immediately on a period of detention.

Temporary treatment is not mentioned in the Act at all. It was instituted by Section 5 of the Mental Treatment Act, 1930 which says that a patient likely to benefit by it may be received as a temporary patient on a written application but without a reception order. The official form of application 'requests' the person in charge of the hospital to receive the patient. The question whether temporary treatment counts as 'care and treatment' under Herbert's Act had often been asked, but has only recently, ten years after the passing of the Act, come before the Court in a pure form.

In *Benson v Benson* (1941, P 90) the respondent was admitted as a temporary patient, and after six months the Board of Control directed the period of treatment to be extended for three months. The patient was discharged relieved before the end of the second period but was admitted at once into another hospital as a voluntary patient. Lord Merriman, the President, found that the direction of the Board extending the period was an order. In the latest case, *Whitley v Whitley* (1946 2 All E R 726), the wife was admittedly incurable and had admittedly been under care and treatment for more than five years. In December, 1936 she was received as a temporary patient shortly after childbirth. After six months she was discharged relieved, but was readmitted as a voluntary patient, and she had been in hospital ever since. There was no such direction as had been made in the *Benson* case as only the initial period of six months was involved. Counsel urged that the procedure by which a patient is admitted to temporary treatment ought to be treated as an order. Mr Justice Barnard, however, could not agree and felt himself bound to deal with the Act as he found it. He could not by any stretch of imagination call an application an order, nor a request an authority. His decision seems logically unassailable, but leads to the absurd position that an extended period of temporary treatment counts for 'divorce' while the original period does not. Although the wife was properly detained as a temporary patient, she was not detained in pursuance of any order.

The judge referred shortly to a case heard a few months earlier, but not then reported in which a relieving officer directed a married woman to be removed to a mental hospital, two days later her husband took her away and she went into another mental institution as a voluntary patient (*Crutchfield v Crutchfield*). Mr Justice Jones said in that case that the relieving officer had not given any order but had merely taken action under Section 20 of the Lunacy Act 1890, and later voluntary treatment therefore did not count for divorce. These two cases provide the latest addition to a long list of amendments which call loudly for insertion in Herbert's Act when Parliament can spare the time.

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

The National Health Service (Scotland) Bill was recommitted on April 21 to a Committee of the whole House of Commons in respect of amendments in the name of the Secretary of State for Scotland.

On Clause 5 Mr WESTWOOD moved an amendment to make clear that the charges to be paid by private patients were to cover the cost falling on public funds. This amendment was accepted.

On Clause 22 Mr WESTWOOD moved to insert a provision that where arrangements provided for the supply of anything prescribed, not being a drug, a medicine, or an appliance of a type normally supplied the local authority may recover from any person so supplied such charge as the authority may determine. He instanced the supply of milk, orange juice, and cod liver oil. He said the Government did not intend to authorize charges for the supply of anything which was provided as an integral part of health treatment. The line was a difficult one to draw, and under the Clause in the form proposed the House of Commons would now determine where the line was to be drawn.

Col WALTER ELLIOT said that under the proposed words the local authority could recover from any person the cost of milk or of cod-liver oil. Nothing discouraged the mothers of young children from applying for such things so much as the long and complicated regulations. He did not believe that the solution proposed by Mr Westwood met the wishes of the House.

Mr WESTWOOD said that responsibility for providing cod liver oil and milk was national and the House was dealing with local authority responsibility.

Sir THOMAS MOORE asked whether, if an iron lung was required and had to be brought from a distance, it had to be paid for by the person who needed it.

Mr BUCHANAN said that was not an appliance supplied by a local authority. The Clause covered purely personal appliances. After further debate the amendment was accepted.

On the motion of Mr WESTWOOD the House agreed to leave out subsection (4) of Clause 22. This amendment deleted from the Bill the provision which sought to make the local health authority the local authority for the purposes of Part I of the Children and Young Persons (Scotland) Act, 1937. An amendment was accepted to Clause 29 to bring into operation on the passing of the Act without waiting for the appointed day a new Clause authorizing local authorities to contribute to expenditure incurred by a body set up to advise on the co-ordination of health services in each area.

On Clause 64 an amendment was accepted on the motion of the Lord Advocate, Mr G R THOMSON authorizing the making of reciprocal arrangements between Scotland and England and Wales or between Scotland and Northern Ireland to safeguard the superannuation rights of persons transferred to employment in health services in those countries. After debate Clause 64 as amended was ordered to stand part of the Bill.

Local Authority Research and Co-ordination

Mr WESTWOOD then brought forward a new Clause enabling local authorities to carry out research connected with their own health service functions. He instanced inquiries into the value of various forms of care or after-care services, studies of the effectiveness of child-welfare centres, and inquiries into the effects of environment on health.

Col ELLIOT saw a danger of overlapping. He pointed out that under the Clause the Regional Hospital Board and the Board of Management would have power to conduct research.

Mr WESTWOOD in reply to questions, said there was a possibility that research being carried on by local authorities might be stopped if the power was not provided in this Clause. If they claimed under the amendment for research which was carried through and the Secretary of State approved the claim they would get grants. The Clause was added to the Bill.

Mr WESTWOOD moved a further new Clause. He said day-to-day co-ordination would be secured by close contact between the personnel responsible for administering the three divisions of the Health Service, and to facilitate liaison the Secretary of State would be in a position to encourage the establishment of non-statutory local committees in which representatives of the three divisions would take part. These committees would not have executive powers but would meet regularly to discuss the whole field of health services for the area, and their findings would go forward as recommendations to the Regional Hospital Boards, the Executive Councils, or the local authorities.

Antuitrin 'S'

A standardized solution of chorionic gonadotrophin

In the female the effect of Antuitrin 'S' is mainly luteinizing, and it is indicated in functional uterine bleeding, dysmenorrhoea, amenorrhoea, oligomenorrhoea and habitual and threatened abortion

In the male, Antuitrin 'S' acts on the interstitial cells of the testes, increasing secretion of the male hormone, and is used in the treatment of cryptorchidism, impotence and aspermia

In both sexes it has been shown to be valuable in delayed puberty, genital infantilism, aene vulgaris, adipose genital dystrophy (Frühlieb's syndrome), and in some cases of sterility

Antuitrin S is supplied in rubber capped vials of 10 c.c. (100 International units per c.c.) and 5 c.c. Concentrated Solution (500 International units per c.c.)

HEPOVITE

A dry granular preparation of Malt and Enzyme Hydrolysed Protein rich in Natural Vitamins

COMPOSITION

Carbohydrate (Maltose) 38% Protein' (N X 6.25) - 50%
(Supplying the amino acids Arginine Histidine Lysine Tryptophane
Phenylalanine Methionine Threonine Leucine Isoleucine Valine
and Cystine)

Each 30 grammes contains

Vitamin A	500 IU	Pan othenic Acid	11.3 mg
Vitamin D	50 IU	Pyridoxin	0.32 mg
Aneurine	10 mg	Biotin	64.8 gamma.
Riboflavin	2.0 mg	Folic Acid	150 gamma.
Nicotinic Acid	6.5 mg	Inositol	81 mg

Choline Calcium Phosphorus and Iron are also present

USES. To correct Nitrogen loss especially when this is due to faulty absorption to supply concurrently complete multiple natural vitamins

DOSAGE Sufficient to provide the required protein supplement (The palatability of Hepovite is such that most patients will readily take any required quantity either neat in milk or sprinkled on a wide range of foods)

SUPPLY Hepovite is not yet available for sale but limited supplies are available for clinical trial by hospitals and clinics

BELLADENAL

Antispasmodic .. Anticonvulsive
:: Sedative ::

BELLADENAL combines the central sedative action of phenobarbitone with the peripheral antispasmodic action of the total laevorotatory alkaloids (Bellafoline) of Belladonna leaves. Bellafoline is only half as toxic as atropine in doses which are therapeutically equivalent in their effect on the parasympathetic.

Each tablet of Belladenal contains

Bellafoline 0.00025 Gm (1/250 grain)

Phenobarbitone 0.05 Gm (3/4 grain)

The components of Belladenal act synergistically with each other so that a powerful antispasmodic and sedative effect is obtained with comparatively small doses.

I-SO-GEL, a granular preparation of certain dried mucilaginous seeds, has the property of reproducing the normal stimulus to intestinal peristalsis by increasing the intestinal bulk, through absorption of water in the alimentary canal.

I-SO-GEL contains no purgatives and is a purely natural laxative with a smooth mechanical action, specially suitable for the constipation of diabetics.

It is valuable also in mucous colitis, dysentery, hæmorrhoids, and intestinal flatulence. After the performance of colostomy, I-so gel gives excellent results by solidifying the faeces.

new Clause authorized a contribution by a local health authority towards expenditure incurred by a co-ordinating committee.

The Clause was read a second time. The Eleventh Schedule was technically amended and the Bill was then reported as amended on recommitment and was immediately considered on Report.

REPORT STAGE

Mr WESTWOOD moved to insert in Clause 5 a proviso that no accommodation shall be set aside (for private patients) unless there will remain available, as part of the hospital and specialist services, for other patients at least as much accommodation as was immediately before the appointed day available free of charge or at hospitals vested in local authorities." He said the object of Clause 5 was to encourage front rank specialists to come into the Service. It enabled specialists to treat patients of their own who wished to continue as private patients in accommodation as physically convenient as possible to the specialist's work for ordinary patients within the Service. The number of specialists was considerably short of the numbers required to provide an efficient service for the whole population. No specialist would be compelled to come into the new Service and it was therefore important that the Secretary of State should do everything to encourage them to spend the maximum time within the Service. Since the Committee Stage he had had discussion with the Scottish specialists which made it clear to him that the success of the new Service would be prejudiced if the facility proposed in the Clause was not extended to them. Other objections had been expressed. On balance it seemed to him the right thing to do was to retain the Clause, but there was no question of so operating it as to reduce the number of beds available free of charge below the number so available immediately before the new Service came into being. Scottish specialists had never suggested such a reduction. He therefore proposed the insertion into the Bill of this proviso which would provide a statutory safeguard against any reduction. He recognized that for a long time it would not be possible to set aside more than a very small proportion of new hospital accommodation or of equivalent accommodation in existing hospitals.

Col ELLIOT said the Opposition accepted the doctrine that the transfer should not diminish the number of free beds available but held also that the transfer should not diminish the number of paying beds available. The Standing Committee on the Bill had felt that paying beds and free beds ought to be mixed and not segregated into nursing homes on one side and hospitals on the other.

Mr BUCHANAN said the amendment safeguarded the present number of free places and that number would be the minimum and not the maximum.

Cmdr GALBRAITH moved to add to the proposed amendment a proviso that accommodation previously used for paying patients should be so set aside unless the result would be to diminish accommodation hitherto available free to patients. His amendment was defeated by 222 to 81 and the amendment moved by Mr Westwood was inserted in the Bill.

Hospital Endowments

On Clause 7 Col ELLIOT moved to provide that the liabilities associated with endowments and to be transferred with them should be such as were reasonably connected with the individual property or properties taken over. Mr BUCHANAN said the Government could not see its way to accept the amendment. It did not know the liabilities concerned. Col ELLIOT appealed to Mr Buchanan to consider whether some form of records could be proposed in the House of Lords to ensure that endowments would not be unreasonably divorced from the original intention of the donors. Mr BUCHANAN said the Government would look into this point again and Col Elliot withdrew his amendment.

Mr BUCHANAN moved to amend Clause 8 by varying the sections to the Hospital Endowments Commission on the principles governing schemes for the management or transfer of endowments. The amendment instructed the Commission to have special regard to the spirit of the intention of the donor or donor and in particular to conditions intended to preserve the memory of any person or class of persons also the extent to which the original purpose of the endowment is provided for by a public service or otherwise and finally the interests of the hospital and specialist services. The amendment was agreed to.

Cmdr GALBRAITH moved to omit from subsection (6) of Clause 8 the words which authorized the Secretary of State in approving any scheme submitted to him by the Hospital Endowments Commission to do so with modifications including any or exceptions. He said it was extraordinary that the Commission should set up an Endowments Commission and yet that

the Secretary of State should take power completely to alter a scheme.

The LORD ADVOCATE said that if this amendment were accepted the Secretary of State would have no latitude at all. If any substantial modification were made which had not been agreed by the Commission the order when laid before Parliament would be accompanied by a White Paper setting out the modifications. By 234 to 76 the House decided to retain the original wording of the Bill.

On Clause 9 the LORD ADVOCATE moved an amendment making less strict the provisions to prevent diversion of hospital funds between the date of publication of the Bill and the appointed day. Col ELLIOT accepted the amendment and said it was an improvement. The House agreed to it.

On Clause 12 Col ELLIOT moved an amendment providing for the laying before Parliament of any scheme dealing with the functions of regional hospital boards and boards of management which had been brought forward by a board and had been modified by the Secretary of State. He said such a provision was more necessary because Mr Westwood had not left the teaching hospitals so far out of the picture as they had been left in the English Bill. The regional boards would have much greater powers in Scotland than in England, and if Mr Westwood had not approved the scheme which had been submitted by a board he should lay this scheme before Parliament.

The LORD ADVOCATE said the amendment would introduce a too formal element into the relationship between the Secretary of State and the regional boards. Other methods of publicity might be utilized instead of the submission of the scheme to Parliament. Col Elliot's amendment was rejected by 235 to 70.

Health Centres

On Clause 15 Col ELLIOT moved to amend the subsection authorizing the Secretary of State to delegate to a local health authority any of his functions under the Clause, such delegation should follow the holding of an inquiry. He said the medical profession would feel more content if the amendment were adopted.

Mr WESTWOOD said he did not intend in the early experimental years of a new service to delegate any health centre functions to local authorities. When the stage of delegating functions was reached the nature of the delegation would be worked out in consultation with the professional people concerned and would not be irrevocable. So far as he was concerned such delegation would never take place except on agreement with the local health authority concerned and after consultation with the Executive Council, medical and other appropriate bodies in the area, and doctors and dentists working at the health centre. A formal inquiry would be too elaborate. Col Elliot withdrew his amendment.

On Clause 27 Mr WESTWOOD secured acceptance of an amendment authorizing a local authority to recover payment for services under this Clause. He instanced the possibility of charges for the supply of extra foodstuffs, fuel, and bedding.

Distribution of Medical Practitioners

On Clause 33 Cmdr GALBRAITH moved to authorize the making of regulations requiring the Scottish Medical Practices Committee to survey each area or part of an area and to report on the number of medical practitioners necessary to provide an adequate service. He said those about to enter the profession should have some knowledge of over-doctored and under-doctored areas.

Mr BUCHANAN could not accept the amendment. A vacancy arising in a district would be advertised in the medical press. In considering whether an area was over-doctored the question of the health of the doctors had to be considered and the mere numbers might be misleading. The Scottish Office took the view that the best way to make vacancies known was by advertisement in the professional journals. The Government would see that the young doctors knew the position throughout Scotland. Mr Westwood would make his officials accessible at all times to the young doctor and they would set the exact picture of the country before him. The amendment was withdrawn.

Mr THORNTON-KEMSLEY on Clause 34 moved to insert a declaration that if premises previously used by a medical practitioner were sold at a public auction by that medical practitioner or by his personal representative such should not be deemed to be a sale of the goodwill or part of the goodwill of the practice of that practitioner. He said that until the hammer fell the seller would not know whether a doctor was going to buy or another man. Once the hammer fell a contract had been made and it would be impossible for the vendor to say that he would not sell to a doctor.

The LORD ADVOCATE held that the amendment was not necessary. Where a doctor's house was sold at a genuine auction, there could be no danger of prosecution. The fact that a sum was paid at such an auction by a purchaser who had no prior agreement with the seller would negative any suggestion that the price contained an element of goodwill. The proposed amendment was rejected by 226 to 70.

On Clause 35 Cmdr GALBRAITH moved to provide that compensation should be payable when the medical practitioner concerned reached the age of 65, or had retired or had died. The Bill before the House recognized only the last two contingencies.

Mr BUCHANAN said the subject had been exhaustively discussed in Standing Committee but he hoped to go some way towards meeting Cmdr Galbraith. At any time, and not only at the age of 65 a doctor, because of overwork or ill health, might wish to sell his practice and buy one of less value. Mr Buchanan reminded the House that he had already agreed that a young doctor going abroad or going into local authority work would get his money as would the young doctor who was overloaded with debts through buying his practice. The Government now proposed to prescribe conditions so that a man who retired because of ill health, to go into a smaller practice might get either the whole or part of his money at once. When a man of 65 retired he retired completely. The case which Mr Buchanan's medical representatives thought should be met was the man who suffered a breakdown in health at 40 to 50 years but who did not wish to retire from work and was seeking an easier life. The Government would meet that class of case at any age by paying the whole or a portion of the sum to which the doctor was entitled. Cmdr Galbraith withdrew his amendment.

Disqualifications and Disputes

On Clause 41 the House accepted an amendment proposed by Mr BUCHANAN authorizing the giving of information to any person who was the subject of an inquiry of the grounds on which any disqualification had been imposed in his case.

The House then rejected by 228 to 71 an amendment proposed by Col ELLIOT on Clause 42. This amendment would have provided that any order made by the Secretary of State dispensing with requirements under the Act should be laid before Parliament.

On Clause 45 Mr BUCHANAN moved to provide that in any dispute the Secretary of State should cause an inquiry to be held at the request of either party, unless satisfied that in the special circumstances such an inquiry was unnecessary. This was accepted.

Drafting amendments were made in Clauses 57 and 63. On Clause 68 the period during which any action or proceedings shall be brought against any authority or officer was changed from two months to twelve months. Formal changes were made in Clause 71, and Mr WESTWOOD gave Col Elliot an assurance that amendments put down by the Opposition to this Clause would be considered before the passage of the Bill through the Lords. An amendment proposed by Cmdr GALBRAITH to ensure that schemes put forward by the Hospital Endowments Commission should be submitted to a positive resolution of both Houses of Parliament was negatived. A drafting amendment was made in Clause 77 to make it clear that the Clause applied only to the use of the word 'asylum' under the Lunacy Act. This concluded the Report Stage and Mr WESTWOOD immediately moved that the Bill be read a third time.

THIRD READING

Mr WESTWOOD said that if the Bill was passed substantially in its present form the Government hoped to fix April 1, 1948, as the appointed day. The Bill put squarely on public authorities the duty to provide all necessary facilities needed for the health care of all the people. The members of the Scottish Health Services Council and its standing advisory committees would be chosen for their ability to give the Secretary of State expert advice on all the problems which would arise in fitting together the various component parts into a unified service, giving everyone access to any kind of specialist treatment which they required. Regional boards and boards of management would be chosen from people with interest in and knowledge of the hospitals they were to administer. The Bill made it possible for the best features of the voluntary hospital system to be maintained. Endowments were left in the hands of the boards of management and regional hospital boards to be expended at their discretion. The Bill placed a duty upon the Secretary of State to provide facilities in the hospital service for the teaching of medicine. It allowed the largest number of hospitals to come into the teaching field and to share in the

advantages which that work could confer. Without any trespassing by the State upon the responsibility of the teaching and licensing authorities the Bill brought these authorities fully into the administration of the hospital service so far as it affected them. Local authorities were given power for important developments in prevention and treatment. In future there would be available to everyone the care and attention of a family doctor of the patient's own choice without any need to count the cost. The Bill did not confer any power to direct individual doctors to work in particular localities or at particular jobs. The passing of the Bill would not produce more doctors overnight, but the organized service which it provided with the new system of remuneration which the Government had in view and the abolition of the sale of practices, would increase the attraction of general medical practice as a career. These factors, in conjunction with measures which the Government were introducing to bring higher education within the reach of all, would supply at no distant date an adequate number of doctors for the tasks ahead.

Centralized Control

Col ELLIOT moved that the House decline to give a Third Reading to a Bill which centralized control of institutions in the hands of the Secretary of State, deprived local authorities and voluntary bodies of powers hitherto exercised to the advantage of the people, took for the Secretary of State power of diverting trust funds and benefactions and gravely threatened the future of the practice of medicine and of research. Col Elliot said the steps which the Government was taking could only be justified if the medical system of Scotland had been a signal failure instead of being, as it admittedly was, one of the great scientific and practising successes of the world. While the Government's plans were waiting to be carried through, the practice of medicine to help the people of Scotland was being held up. The stereotyping of research into a Government system where the subject became political was a strong argument against the Bill.

Mr RANKIN said the Bill would not interfere with the training of students and it would be possible to absorb at once in active work in the hospitals every young doctor who left the universities. He believed at the moment there was such plenitude of doctors that they could not be placed in private practice.

Lady GRANT held that the abolition of the sale of goodwill of practices and the introduction of the element of basic salary opened the way to the full State salaried service which was the acknowledged aim of Labour Members.

Democratic Research

Dr H B MORGAN said the people of Scotland had not for years received a good medical service. The Bill was a better one than the English Bill. He did not deny the pre-eminence of the Scottish medical schools, but it did not follow that the schools must remain under the old system. He was glad Mr Westwood was taking medical research into his hands. If he put some democratic non-medical people on the medical research body, he would find them to be more useful as representing the working classes than the medical men who were trained as research workers.

Lord WILLIAM SCOTT recalled that when he joined the board of a London hospital he found that there were no doctors on the board of management. He was told that the patients and the medical officers did not like the presence of doctors on the board. It seemed to him that those to be nominally in charge of the hospital system of Scotland would have immediate responsibility and little power.

Mr McALLISTER said he was not satisfied with the Bill as it stood when it came to the wider aspects of medicine, but he thought the Bill the Scottish people would no longer have to fear what would happen when they fell ill.

Sir WILLIAM DARLING said the Bill was setting up eight committees to look after the health services of Scotland and the Tribunal which was to look after the doctor criminal created by the Bill.

Mr GALLACHER said the Bill put so much power into the hands of the Secretary of State that it would require a gentle and imaginative Secretary of State in close touch with the people.

Major McCALLUM said in the Bill the House saw the last of the medical service which for years past had done good in the Highlands and Islands of Scotland. Mr Westwood said that service would be swallowed up.

Mr WESTWOOD denied this. He had said that this service had been so successful that it had been the basis of the Government scheme for the rest of Scotland.

Cmdr GALBRAITH said the Secretary of State was to stick his finger in every pie and was taking upon himself the duty

providing facilities for clinical teaching and of deciding what was necessary to meet these needs. It was obvious that the advice he would receive on the subject would only be the advice of his own Department. The setting up of the medical education committees giving advice to the regional boards was something of a pretence. People well qualified to judge received these proposals with dismay. The Bill sapped the independence of the doctor.

Highlands and Islands

Mr BUCHANAN said there was a State medical service now in the Highlands and Islands which was far ahead of anything connected with private practice or panel patients throughout Scotland.

Major McCALLUM said that doctors in the Highlands and Islands medical scheme were private doctors semi-subsidized by the State.

Mr BUCHANAN said not a single servant in this scheme had made any representation against this Bill through the British Medical Association, to the Secretary of State, or to the Chief Medical Officer. He pointed out that when it was a question of dealing with notifiable disease the State did all. There were no voluntary associations for infectious diseases and no running about with tin boxes for those hospitals. The Government was going to increase the opportunities for research. He did not think that in two or three years the Bill would end the shortage of beds throughout Scotland, all he did say was that if the voluntary hospitals were left to do it by voluntary effort it would take much longer. The voluntary hospital in Scotland to-day could not exist if almost 80% of its income did not come from local authorities or State sources. The "free choice" of doctor was limited to a doctor who happened to practise in a particular area. Under a State scheme the choice would be wider than at present. There had been talk about doctors working a shift system. One of the things he had always desired was to see ordinary medical men get something like reasonable hours of work. Nearly every working-class M.P. or Glasgow had received representations that it was almost impossible to get a doctor on a Tuesday afternoon or on a Friday.

The Government thought that the Bill could be made workable and that it was a good proposition. The arrangement as regards hospital treatment under a regional board was easy and flexible but a great deal would turn on the humanity of the Secretary of State and his officials. Much of the success of the scheme would depend on the vigilance of the House of Commons and of the Secretary of State. Questions had been asked about the nature-cure doctors. He had no objection to these practitioners. If they got clients who said they wanted a nature doctor he would have no objection. He had been asked what was the future of the State medical service. All he said that night was that the Government pinned its faith to this Bill. What might be done in five or ten years would be decided first by the electorate and then by the Government of the day.

Col Elliott's amendment was rejected by 143 to 54 and the Bill was read a third time.

The National Health Service (Scotland) Bill had its Second Reading in the House of Lords on May 1. A report of the Bill will appear in our next issue.

Doctors Cars—Mr C. N. SHAWCROSS on April 21, asked whether the Minister of Supply knew that the efforts of the motor industry to give preference in the delivery of motor-cars required by doctors had proved ineffective. Many doctors urgently in need of motor-cars for their professional duties were unable to obtain them. Would he consider with the industry a scheme of covenants similar to the scheme prohibiting resale of motor-cars within twelve months, under which motor dealers were obliged to give priority of delivery to the doctors? Mr WILKINSON replied: No, sir. The motor industry is honouring its undertaking to give preference to the delivery of cars required by doctors while having regard to the claims of the general public, nurses, and midwives.

Calorie—According to Mr Strachey the latest figure of calories per head of the population was for December, 1946. It was based on a small but representative sample of working-class families and covered only food eaten in the home and not school or any meals taken out of the home. The figure was 2,300 calories, compared with an average of 2,390 in December, 1945.

Vacuum Flasks—5 prices of vacuum flasks are now set nearly 100% above the standard. Until they are the Board of Trade cannot do anything about the price scheme.

Radiative Substances Bill—The Radiative Substances Bill was introduced by Lord James of Harewood in the House of Lords on April 24.

Medical News

Mr Arthur G. Enock, M.I. Mech. E. will give a lecture on Practical Standards in Milk Treatment and Distribution, on Tuesday, May 6, at 5.30 p.m., at the L.C.C. Smithfield College of Food Technology, Eagle Court, St. John's Lane, London, E.C.1. All interested in the milk industry are invited to attend.

A choral and orchestral concert will be given by the Music Society of Central London Electricity, Ltd., in aid of the British Empire Nurses' War Memorial Fund on May 6 at 7 p.m. at the Kingsway Hall, W.C.2. The programme includes works by Handel and Schubert. Tickets 2s to 10s 6d by post from the Fund, 36 Kingsway, W.C.2 or from the Kingsway Hall on the night of the performance.

A meeting of the Society of Public Analysts and Other Analytical Chemists will be held at the Chemical Society's rooms (Burlington House, Piccadilly, London, W.) on Wednesday, May 7, at 6 p.m. when a paper on "A Microchromatographic Method for the Detection and Approximate Determination of the Different Penicillins in a Mixture" will be presented by Drs. R. R. Goodall and A. A. Levi. The paper will be preceded by a brief account of the chemical nature of the penicillins by Mr F. A. Robinson.

The forty-eighth annual meeting of the Association of Sea and Air Port Health Authorities of the British Isles will be held at Belfast City Hall on Tuesday, Wednesday, and Thursday, May 13, 14, and 15. The meeting will open at 10 a.m. on May 13 with a civic welcome by the Lord Mayor of Belfast, and at 12 noon Mr James Alexander will read a paper on "The History and Development of the Port and Harbour of Belfast". On May 14 at 10 a.m., Dr Lloyd Hughes will present a paper on "Hygiene of Crews' Quarters and Provisions," and at 11 a.m. Sir Alexander Macgregor will describe "Twenty Years of Port Medical Administration in Glasgow". On May 15 papers will be read by Dr Samuel Barron, at 10 a.m., on "The Sanitary Control of Foreshores of Belfast Lough", by Dr Melville Mackenzie at 11 a.m., on "International Health", and by Dr W. G. Swann, at 11.45 a.m., on "Problems of Health Control at an Air Port".

The Council of the Society of Medical Officers of Health is giving a luncheon to its chairman, Dr George F. Buchan, on Friday, May 16, at the Piccadilly Hotel, London, W.1, on his retirement from office as M.O.H. for the borough of Willesden. The occasion will also celebrate the election of Dr Buchan as an Honorary Fellow of the Society as a person "eminently distinguished in the advancement of public health". The attendance of other old friends and colleagues of Dr Buchan will be welcome. Tickets will cost 16s (inclusive of tips but not of wines), and applications should be made to the Executive Secretary, Society of Medical Officers of Health, Tavistock House South, Tavistock Square, London, W.C.1.

St. George's Hospital held its annual service in the chapel on St. George's Day, April 23. The Lord Bishop of St. Albans delivered the address and the Matron, Miss Helen Hanks, who is leaving shortly after 37 years' service unveiled a plaque dedicated to the memory of the doctors and nurses associated with the hospital who died as a result of enemy action during the recent war. After the service there was an informal reunion in the board room, and on May 11 a service will be held in the chapel for the relatives of the men and women in whose memory the plaque has been erected.

The Right Hon. J. A. Beasley, High Commissioner for Australia, unveiled a wall plaque at the L.C.C.'s King George V Hospital, Godalming, Surrey, on April 14. It has been erected to commemorate the occupation of the hospital by members of the Third Australian General Hospital in 1940-1 and as a tribute to the part the Commonwealth Forces took in the second world war. The plaque has been provided out of a gift to the King George V Hospital by the Australian Red Cross Society of £150 as an expression of the society's gratitude for all that was done for sick and wounded Australians during the war. The rest of the money has been used to provide two radiograms for use in the staff common sitting rooms.

A clinic for psychotherapy has been started by the Society of Analytical Psychology, Ltd., 32 Carlton Hill, St. John's Wood, London, N.W.8 (Maida Vale 7039). The clinic is open on Mondays and Thursdays. All interviews should be made by appointment. The Society has also formulated a syllabus of training for analysts. This includes a personal and training analysis of at least three years followed by a period of work under supervision. All particulars in regard to the clinic, the training of analysts and other activities of the Society may be obtained from the Secretary.

In our advertisement columns this week the Royal College of Surgeons of England invites applications for the post of lecturer in physiology at a salary of £800 per annum.

The LORD ADVOCATE held that the amendment was not necessary. Where a doctor's house was sold at a genuine auction, there could be no danger of prosecution. The fact that a sum as paid at such an auction by a purchaser who had no prior agreement with the seller would negate any suggestion that the price contained an element of goodwill. The proposed amendment was rejected by 226 to 70.

On Clause 35 Cmdr GALBRAITH moved to provide that compensation should be payable when the medical practitioner concerned reached the age of 65, or had retired or had died. The Bill before the House recognized only the last two contingencies.

Mr BUCHANAN said the subject had been exhaustively discussed in Standing Committee but he hoped to go some way towards meeting Cmdr Galbraith. At any time, and not only at the age of 65 a doctor, because of overwork or ill health, might wish to sell his practice and buy one of less value. Mr Buchanan reminded the House that he had already agreed that a young doctor going abroad or going into local authority work would get his money as would the young doctor who was overloaded with debts through buying his practice. The Government now proposed to prescribe conditions so that a man who retired because of ill-health to go into a smaller practice might get either the whole or part of his money at once. When a man of 65 retired he retired completely. The case which Mr Buchanan's medical representatives thought should be met was the man who suffered a breakdown in health at 40 to 50 years but who did not wish to retire from work and was seeking an easier life. The Government would meet that class of case at any age by paying the whole or a portion of the sum to which the doctor was entitled. Cmdr Galbraith withdrew his amendment.

Disqualifications and Disputes

On Clause 41 the House accepted an amendment proposed by Mr BUCHANAN authorizing the giving of information to any person who was the subject of an inquiry of the grounds on which any disqualification had been imposed in his case.

The House then rejected by 228 to 71 an amendment proposed by Col ELLIOT on Clause 42. This amendment would have provided that any order made by the Secretary of State dispensing with requirements under the Act should be laid before Parliament.

On Clause 45 Mr BUCHANAN moved to provide that in any dispute the Secretary of State should cause an inquiry to be held at the request of either party, unless satisfied that in the special circumstances such an inquiry was unnecessary. This was accepted.

Drafting amendments were made in Clauses 57 and 63. On Clause 68 the period during which any action or proceedings shall be brought against any authority or officer was changed from two months to twelve months. Formal changes were made in Clause 71, and Mr WESTWOOD gave Col Elliot an assurance that amendments put down by the Opposition to this Clause would be considered before the passage of the Bill through the Lords. An amendment proposed by Cmdr GALBRAITH to ensure that schemes put forward by the Hospital Endowments Commission should be submitted to a positive resolution of both Houses of Parliament was negatived. A drafting amendment was made in Clause 77 to make it clear that the Clause applied only to the use of the word 'asylum' under the Lunacy Act. This concluded the Report Stage and Mr WESTWOOD immediately moved that the Bill be read a third time.

THIRD READING

Mr WESTWOOD said that if the Bill was passed substantially in its present form the Government hoped to fix April 1, 1948, as the appointed day. The Bill put squarely on public authorities the duty to provide all necessary facilities needed for the health care of all the people. The members of the Scottish Health Services Council and its standing advisory committees would be chosen for their ability to give the Secretary of State expert advice on all the problems which would arise in fitting together the various component parts into a unified service giving everyone access to any kind of specialist treatment which they required. Regional boards and boards of management would be chosen from people with interest in and knowledge of the hospitals they were to administer. The Bill made it possible for the best features of the voluntary hospital system to be maintained. Endowments were left in the hands of the boards of management and regional hospital boards to be expended at their discretion. The Bill placed a duty upon the Secretary of State to provide facilities in the hospital service for the teaching of medicine. It allowed the largest number of hospitals to come into the teaching field and to share in the

advantages which that work could confer. Without any trespassing by the State upon the responsibility of the teaching and licensing authorities the Bill brought these authorities fully into the administration of the hospital service so far as it affected them. Local authorities were given power for important developments in prevention and treatment. In future there would be available to everyone the care and attention of a family doctor of the patient's own choice without any need to count the cost. The Bill did not confer any power to direct individual doctors to work in particular localities or at particular jobs. The passing of the Bill would not produce more doctors overnight, but the organized service which it provided with the new system of remuneration which the Government had in view and the abolition of the sale of practices, would increase the attraction of general medical practice as a career. These factors in conjunction with measures which the Government were introducing to bring higher education within the reach of all, would supply at no distant date an adequate number of doctors for the tasks ahead.

Centralized Control

Col ELLIOT moved that the House decline to give a Third Reading to a Bill which centralized control of institutions in the hands of the Secretary of State, deprived local authorities and voluntary bodies of powers hitherto exercised to the advantage of the people, took for the Secretary of State power of diverting trust funds and benefactions and gravely threatened the future of the practice of medicine and of research. Col Elliot said the steps which the Government was taking could only be justified if the medical system of Scotland had been a signal failure instead of being, as it admittedly was, one of the great scientific and practising successes of the world. While the Government's plans were waiting to be carried through, the practice of medicine to help the people of Scotland was being held up. The stereotyping of research into a Government system where the subject became political was a strong argument against the Bill.

Mr RANKIN said the Bill would not interfere with the training of students and it would be possible to absorb at once in active work in the hospitals every young doctor who left the universities. He believed at the moment there was such a plenitude of doctors that they could not be placed in private practice.

Lady GRANT held that the abolition of the sale of goodwill of practices and the introduction of the element of basic salary opened the way to the full State salaried service which was the acknowledged aim of Labour Members.

Democratic Research

Dr H B MORGAN said the people of Scotland had not for years received a good medical service. The Bill was a better one than the English Bill. He did not deny the pre-eminence of the Scottish medical schools, but it did not follow that the schools must remain under the old system. He was glad Mr Westwood was taking medical research into his hands. If he put some democratic non medical people on the medical research body, he would find them to be more useful as representing the working classes than the medical men who were trained as research workers.

Lord WILLIAM SCOTT recalled that when he joined the board of a London hospital he found that there were no doctors on the board of management. He was told that the patients and the medical officers did not like the presence of doctors on the board. It seemed to him that those to be nominally in charge of the hospital system of Scotland would have immediate responsibility and little power.

Mr MCALLISTER said he was not satisfied with the Bill as it stood when it came to the wider aspects of medicine but under the Bill the Scottish people would no longer have to fear what would happen when they fell ill.

Sir WILLIAM DARLING said the Bill was setting up eight committees to look after the health services of Scotland including the Tribunal which was to look after the doctor-criminal created by the Bill.

Mr GALLACHER said the Bill put so much power into the hands of the Secretary of State that it would require an intelligent and imaginative Secretary of State in close touch with the people.

Major MCCALLUM said in the Bill the House saw the last of the medical service which for years past had done good work in the Highlands and Islands of Scotland. Mr Westwood had said that service would be swallowed up.

Mr WESTWOOD denied this. He had said that this service had been so successful that it had been the basis of the Government scheme for the rest of Scotland.

Cmdr GALBRAITH said the Secretary of State was to have his finger in every pie and was taking upon himself the duty of

providing facilities for clinical teaching and of deciding what was necessary to meet these needs. It was obvious that the advice he would receive on the subject would only be the advice of his own Department. The setting up of the medical education committees giving advice to the regional boards was something of a pretence. People well qualified to judge received these proposals with dismay. The Bill sapped the independence of the doctor.

Highlands and Islands

Mr BUCHANAN said there was a State medical service now in the Highlands and Islands which was far ahead of anything connected with private practice or panel patients throughout Scotland.

Major MCCALLUM said that doctors in the Highlands and Islands medical scheme were private doctors semi-subsidized by the State.

Mr BUCHANAN said not a single servant in this scheme had made any representation against this Bill, through the British Medical Association, to the Secretary of State, or to the Chief Medical Officer. He pointed out that when it was a question of dealing with notifiable disease the State did all. There were no voluntary associations for infectious diseases and no running about with tin boxes for those hospitals. The Government was going to increase the opportunities for research. He did not claim that in two or three years the Bill would end the shortage of beds throughout Scotland, all he did say was that if the voluntary hospitals were left to do it by voluntary effort it would take much longer. The voluntary hospital in Scotland to-day could not exist if almost 80% of its income did not come from local authorities or State sources. The free choice of doctor was limited to a doctor who happened to practise in a particular area. Under a State scheme the choice would be wider than at present. There had been talk about doctors working a shift system. One of the things he had always desired was to see ordinary medical men get something like reasonable hours of work. Nearly every working class M.P. for Glasgow had received representations that it was almost impossible to get a doctor on a Tuesday afternoon or on Sundays.

The Government thought that the Bill could be made workmanlike and that it was a good proposition. The arrangement in regard to hospital treatment under a regional board was easy and flexible, but a great deal would turn on the humanity of the Secretary of State and his officials. Much of the success of the scheme would depend on the vigilance of the House of Commons and of the Secretary of State. Questions had been raised about the nature-cure doctors. He had no objection to these practitioners. If they got clients who said they wanted a nature doctor he would have no objection. He had been asked what was the future of the State medical service. All he said that night was that the Government pinned its faith to his Bill. What might be done in five or ten years would be decided first by the electorate and then by the Government of the day.

Col Elliot's amendment was rejected by 143 to 54 and the Bill was read a third time.

The National Health Service (Scotland) Bill had its Second Reading in the House of Lords on May 1. A report of the debate will appear in our next issue.

Doctors Cars—Mr C. N. SHAWCROSS on April 21, asked whether the Minister of Supply knew that the efforts of the motor industry to give preference in the delivery of motor-cars required by doctors had proved ineffective. Many doctors urgently in need of motor-cars for their professional duties were unable to obtain them. Would he consider with the industry a scheme of covenants similar to the scheme prohibiting resale of motor-cars within twelve months, whereby motor dealers were obliged to give priority of delivery to such doctors? Mr WILMOT replied "No sir." The motor industry was honouring its undertaking to give preference to the delivery of cars required by doctors, while having regard to the claims of the other priority users, nurses and midwives.

Calories—According to Mr Strachey the latest figure of calorie intake per head of the population was for December 1946. It was based on a small but representative sample of working-class families and covered only food eaten in the home and not school or any other meals taken out of the home. The figure was 2,300 calories, which compared with an average of 2,390 in December, 1945.

Vacuum Flasks—Supplies of vacuum flasks are not yet nearly equal to the demand. Until they are the Board of Trade cannot agree to drop the permit scheme.

Isotopes—The Radioactive Substances Bill was introduced by Lord Inman Lord Privy Seal, in the House of Lords on April 24 and was read a first time.

Medical News

Mr Arthur G. Enock, M.I.Mech.E., will give a lecture on Practical Standards in Milk Treatment and Distribution, on Tuesday May 6, at 5.30 p.m. at the L.C.C. Smithfield College of Food Technology, Eagle Court, St John's Lane London, E.C1. All interested in the milk industry are invited to attend.

A choral and orchestral concert will be given by the Music Society of Central London Electricity, Ltd., in aid of the British Empire Nurses' War Memorial Fund on May 6 at 7 p.m. at the Kingsway Hall, W.C2. The programme includes works by Handel and Schubert. Tickets 2s to 10s 6d by post from the Fund, 36 Kingsway, W.C2 or from the Kingsway Hall on the night of the performance.

A meeting of the Society of Public Analysts and Other Analytical Chemists will be held at the Chemical Society's rooms (Burlington House, Piccadilly, London, W.) on Wednesday, May 7, at 6 p.m. when a paper on "A Micro-chromatographic Method for the Detection and Approximate Determination of the Different Penicillins in a Mixture" will be presented by Drs. R. R. Goodall and A. A. Levi. The paper will be preceded by a brief account of the chemical nature of the penicillins by Mr F. A. Robinson.

The forty-eighth annual meeting of the Association of Sea and Air Port Health Authorities of the British Isles will be held at Belfast City Hall on Tuesday, Wednesday and Thursday, May 13, 14, and 15. The meeting will open at 10 a.m. on May 13 with a civic welcome by the Lord Mayor of Belfast, and at 12 noon Mr James Alexander will read a paper on "The History and Development of the Port and Harbour of Belfast." On May 14 at 10 a.m. Dr Lloyd Hughes will present a paper on "Hygiene of Crews Quarters and Provisions," and at 11 a.m. Sir Alexander Macgregor will describe "Twenty Years of Port Medical Administration in Glasgow." On May 15 papers will be read by Dr Samuel Barron, at 10 a.m., on "The Sanitary Control of Foreshores of Belfast Lough," by Dr Melville Mackenzie, at 11 a.m. on "International Health," and by Dr W. G. Swann, at 11.45 a.m. on "Problems of Health Control at an Air Port."

The Council of the Society of Medical Officers of Health is giving a luncheon to its chairman, Dr George F. Buchan, on Friday, May 16, at the Piccadilly Hotel, London, W.1, on his retirement from office as M.O.H. for the borough of Willesden. The occasion will also celebrate the election of Dr Buchan as an Honorary Fellow of the Society as a person "eminently distinguished in the advancement of public health." The attendance of other old friends and colleagues of Dr Buchan will be welcome. Tickets will cost 16s (inclusive of tips but not of wines), and applications should be made to the Executive Secretary, Society of Medical Officers of Health Tavistock House South Tavistock Square London, W.C1.

St George's Hospital held its annual service in the chapel on St George's Day, April 23. The Lord Bishop of St Albans delivered the address and the Matron, Miss Helen Hanks, who is leaving shortly after 37 years' service unveiled a plaque dedicated to the memory of the doctors and nurses associated with the hospital who died as a result of enemy action during the recent war. After the service there was an informal reunion in the board room, and on May 11 a service will be held in the chapel for the relatives of the men and women in whose memory the plaque has been erected.

The Right Hon. J. A. Beasley, High Commissioner for Australia, unveiled a wall plaque at the L.C.C.'s King George V Hospital Godalming Surrey, on April 14. It has been erected to commemorate the occupation of the hospital by members of the Third Australian General Hospital in 1940-1 and as a tribute to the part the Commonwealth Forces took in the second world war. The plaque has been provided out of a gift to the King George V Hospital by the Australian Red Cross Society of £150 as an expression of the society's gratitude for all that was done for sick and wounded Australians during the war. The rest of the money has been used to provide two radiograms for use in the staff common sitting rooms.

A clinic for psychotherapy has been started by the Society of Analytical Psychology Ltd. 32 Carlton Hill St John's Wood London, N.W.8 (Maida Vale 7039). The clinic is open on Mondays and Thursdays, all interviews should be made by appointment. The Society has also formulated a syllabus of training for analysts. This includes a personal and training analysis of at least three years, followed by a period of work under supervision. All particulars in regard to the clinic, the training of analysts and other activities of the Society may be obtained from the Secretary.

In our advertisement columns this week the Royal College of Surgeons of England invites applications for the post of lecturer in physiology at a salary of £800 per annum.

A large scale attack on tuberculosis is to be begun in South Africa with the aid particularly of BCG vaccine and the vole bacillus vaccine developed by Dr A P Wells who is at present in Durban. Work on the latter bacillus which causes a fatal disease in wild voles was carried out at the King George V Hospital in Durban during the war. Dr B A Dormer, Chief Tuberculosis Officer for South Africa emphasizes that before these vaccines can be widely used much preliminary epidemiological investigation is necessary.

The Secretary of State for Scotland and the Minister of Health have set up a working party to inquire into the recruitment and training of midwives and any other matters which have a bearing on the present shortage of practising midwives. The chairman is Mrs Mary Stocks, BSc, Principal of Westfield College, London. Assisting the working party is a steering committee, also under the chairmanship of Mrs Stocks. All correspondence, including any suggestions from interested organizations, should be addressed to the Secretary of the Midwifery Inquiry, Ministry of Health, Whitehall, London SW 1.

Dr Eleanor H Kelly has been appointed a Justice of the Peace for Wimbledon and was recently elected a member of the Merton and Morden Urban District Council.

Dr Peter McBride, of York, who died on June 16, 1946 left £85,736. Prof W Gemmill, of Birmingham Professor of Surgery in Birmingham University, who died on July 28, 1946 left personal estate in England and Scotland valued at £67,568. Prof J W W Stephens, of Ferry-side Carmarthenshire, Emeritus Professor of Tropical Medicine, Liverpool University, who died on May 17, 1946, aged 81 years left £16,792. Dr Ilja Margolin, of Birmingham who died on June 28, 1946 left £10,311. Dr Ernest Millam, of Oxford, who died on Oct 24, 1946 left £47,588. Dr George Alexander Troup Aberdeenshire who died on Oct 24, 1946, left £32,820. Sir William J Collins, who died on Dec 12, 1946, left £33,272. Mr Arthur Tudor Edwards, who died on Aug 25, 1946, left £52,472. Prof T Wardrop Griffiths, of Leeds Emeritus Professor of Medicine, Leeds University, who died on Oct 21, 1946, left £49,478.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* increases were reported in the notifications of measles 1,983 dysentery 33, and diphtheria 29 while there was a fall in the incidence of scarlet fever 67 and of whooping-cough 24.

A rise in the notifications of measles was recorded in most areas: the largest increases were Yorkshire West Riding 329, Staffordshire 171, Leicestershire 160 Lancashire 138 Glamorganshire 110 and Warwickshire 107. Only slight changes appeared in the local trends of scarlet fever and diphtheria. The local incidence of whooping cough fluctuated but the general tendency was for an increased incidence in the south and a decrease in the north, the largest rise was Kent 51 and the largest fall Lancashire 64. The increase in cases of dysentery was due to an outbreak involving 25 persons in Surrey (Woking U.D. 21).

In *Scotland* there was a decrease in the incidence of whooping-cough 52 measles 31, and dysentery 10. Notifications increased for scarlet fever 22 diphtheria 13 and cerebrospinal fever 11. The increase in cases of diphtheria was confined to Glasgow, where the incidence rose from 11 to 32. The rise in the notifications of cerebrospinal fever was contributed by the western area of the country.

In *Eire* the chief features of the returns were rises in the incidence of whooping cough 33 and diarrhoea and enteritis 21: these increases were contributed by Dublin C.B.

In *Northern Ireland* infectious diseases were less prevalent during the week and small declines were recorded for most diseases.

Births and Deaths During the March Quarter

The number of births registered during the first quarter of this year in England and Wales was 241,421 equivalent to a rate of 22.8 per 1,000. This was the highest rate since the second quarter of 1921 and was 6.7 above the average of the first quarters of 1941-5. The death rate was 17.2 per 1,000, and was 2.5 above the rate of the first quarter of 1945 and 2.4 above the 1941-5 average.

Week Ending April 19

The notifications of infectious diseases in England and Wales during the week included scarlet fever 930 whooping-cough 2,117 diphtheria 182 measles 9,035 acute pneumonia 728, cerebrospinal fever 81 dysentery 46 acute poliomyelitis 9, smallpox 2, paratyphoid 5, typhoid 5.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 12.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths recorded under each infectious disease are for (a) The 126 principal towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

* Measles and whooping-cough are not notifiable in Scotland and the are therefore an approximation only.

† Includes primary form for England and Wales (London & county) and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Artificial Insemination

Q—A patient of mine wishes to be artificially inseminated. A suitable donor has been obtained. When should artificial insemination be performed and exactly what technique should be used ?

A—If the donor is already selected it is perhaps rather late to offer advice on this point. Experience has shown, however, that it is important that he and the patient should remain anonymous to each other. Their blood groups should be known if only to exclude Rh incompatibility, and his seminal fluid should have been fully analysed and also cultured to exclude infection in his genital tract. For the purpose of insemination the semen should be collected by masturbation into a dry glass container whose interior is sterile. It should be kept at atmospheric temperature during the interval between collection and injection, which should not exceed three hours and is preferably less.

If the genital organs of the woman are normal, the technique of injection is comparatively simple. The cervix is exposed by inserting an unlubricated speculum into the vagina, any discharge is wiped away but no antiseptic should be used. A small quantity of semen, not more than 1.0 ml (0.1 to 0.2 ml is adequate) is drawn up into a dry and sterilized syringe and is injected slowly and with minimal pressure just within the cervical canal. Most of it escapes back into the upper vagina. The patient should remain lying flat for about five minutes afterwards.

If artificial insemination is indicated, then it will only be effective if performed at about the time of ovulation. This can sometimes be roughly determined from daily records of the waking vaginal or rectal temperature, the occurrence of ovulation being indicated by a fall followed by a sharp rise within twenty-four hours. Ovulation pain or haemorrhage may also be a useful guide. If it is impracticable to determine the time of ovulation then insemination should be repeated every two or three days between the eighth and eighteenth days of a twenty-eight day cycle, i.e., four or five times in all. It should be realized moreover that insemination may have to be carried out during several monthly cycles before a pregnancy results.

Finally attention should be drawn to the medico-legal aspects of this procedure. They are considered in a leading article elsewhere in this issue (p. 605).

"Faecal B. Coli"

Q—The term 'faecal B. coli' is often used in bacteriological reports. Is there a B. coli which is not faecal? Does the term imply that the organism is of human origin? I believe that human B. coli cannot be distinguished from those of animal origin.

A—The term *B. coli* in its widest sense includes the large number of related strains and species forming the coli-aerogenes group of the genus *Bacterium*. Most of these organisms fall into one of two main subdivisions: (1) the faecal *B. coli* which commonly frequent the intestinal tract of man and animals, (2) the non-faecal *B. coli* which usually exist as free living forms associated with soil water and plants. Therefore many *B. coli* cur which are not faecal, those which are not faecal are widely distributed as animal parasites. There is no constant distinction between strains of human and those of animal origin. It is only to be expected each habitat is to a limited extent interchangeable and bacilli having intermediate characteristics are sometimes encountered. In spite of this it is useful in public health work to determine to which group contaminants in milk and drinking water belong. This broad distinction is based on a study of the organism's biochemical reactions. Non-faecal *B. coli* from such sources have very much less significance

than those of faecal type since the presence of the latter implies probable faecal pollution and all the risks of infection with intestinal pathogens which this may entail.

Intermittent Claudication

Q—I have read that the Americans have had excellent results from injections of vitamin C and histidine in intermittent claudication. Has it been tried in this country?

A—This question evidently refers to the preliminary report of Wirtschafter and Widman (*J. Amer. med. Ass.* 1947, 133, 604) on the treatment of eleven cases of peripheral vascular disease with histidine and ascorbic acid. The rationale of the treatment is that ascorbic acid converts histidine slowly into histamine, which acts as a vasodilator. These authors give 500 mg of sodium ascorbate intravenously followed by 5 ml of a 4% solution of histidine hydrochloride intramuscularly and 100 mg of sodium ascorbate intravenously. Treatment is repeated every 4, 6, 8, or 12 hours according to the severity of the condition. So far as we are aware the method has not been tried in this country.

Edentulous Halitosis

Q—Since having all her teeth extracted for dental sepsis a patient has complained of an unpleasant taste in the mouth and notices a film on her dentures. It is temporarily relieved after meals and by mouth-washes. The tongue, buccal mucosa and pharynx appear normal. What treatment is recommended?

A—Occasionally a small fragment of tooth root left behind during extractions is to blame in such cases. A small sinus may be found from which pus can be expressed. In consequence it is always advisable to have a full set of dental x-ray films in such a case to exclude the presence of any retained roots. Should no such obvious cause be present to account for the unpleasant taste, the denture itself is sometimes to blame. Some patients do not tolerate vulcanite well, and trouble sometimes occurs where the rubber has not been thoroughly vulcanized. In these cases it is worth trying an acrylic resin denture. The latter type however, sometimes itself gives rise to a taste where the resin has not been thoroughly processed.

Burnt Nipple and Lactation

Q—A patient now aged 23 suffered a burn in early childhood involving the nipple and areola of the right breast. The nipple is considerably smaller than that of the other side, and the openings of the lactiferous ducts appear to be obliterated. Can a nipple which will function be established?

A—There is no known method of establishing new openings to lactiferous ducts which have been obliterated as a result of a burn in early childhood. If, however, the nipple is present as in this case, it is likely that some degree of lactation may prove possible, as a few remaining ducts may communicate with secretory tissue.

Death Rates, 1936-46

Q—How does the present death rate compare with the pre-war rate and with that during the war?

A—The crude death rate of 11.5 per 1,000 in 1946 was below the average of the immediate pre-war years and the average of the war years. The death rate during 1936-9 varied from 11.6 to 12.4 and during 1940-4 the death rate ranged from 11.5 to 13.9.

Penicillin Desensitization

Q—A patient has had severe reactions to various forms of penicillin treatment, also a violent eczematous reaction following a subcutaneous test dose of the drug. I should like to know if desensitization to penicillin has been undertaken. Is the immunity of a lasting type? Does desensitization of the tissue cells lead to any insensitivity of the infecting organisms to the drug thus reducing its therapeutic efficacy?

A—O. Donovan and Klorfaja (*Lancet* 1946, 2, 444) desensitized a patient by giving 15,000 units by mouth several times a day for a fortnight. There is no reason to suppose that anyone who has ceased to be sensitive will spontaneously become so again, though further treatment might, of course, reproduce

condition. There is no connexion whatever between tissue activity and the susceptibility of micro organisms to penicillin, hence there is no danger that desensitization would lead to any impairment of therapeutic effect.

Pediculosis

Q—*Are there other hosts than man for *Pediculus capitis* and *corporis* and *Phthirus pubis*? If so what?*

A—There are no other natural hosts than man. Some American workers have shown that *P. humanus corporis* can be reared with considerable difficulty on the rabbit (Davis and Hansens, *Amer J Hyg* 1945, 41 1). The abdomen was shaved daily and the lice fed two or three times a day. Even so there was a high mortality, though it was just possible to rear two generations on this host.

Sexual Frigidity

Q—*Is there any remedy for a fertile young married woman with markedly subnormal sexual desire associated with abnormal sleepiness? She is otherwise normal. Could the condition have an endocrine basis?*

A—Sexual frigidity is rarely due to an endocrine cause, and more often is the result of a faulty outlook on sex matters or a failure on the part of the husband to rouse the sex-urge, which usually is latent in women and has to be developed by careful and patient education. In this case, however, the association of sleepiness raises the possibility of a hypothalamic or hypothalamic pituitary disorder. The fact that she is fertile is evidence against any gross pituitary fault, but a lesion in the central nervous system should be excluded, so also should hypothyroidism. If no organic cause can be found hormone therapy is not likely to help, and the first step should be to make sure that the husband is fully aware of his duties in respect of love-making, one of the many books on the subject might help him. There should also be careful inquiry into the past history of the wife to see if there is any factor in her upbringing or any experience in earlier years which has given her a revulsion to the physical side of marriage.

Tests of Paternity

Q—*Is there any reliable method of proving the paternity of a child who bears a strong resemblance to a suspected party and none at all to the supposed father?*

A—No test yet devised will positively assign paternity to a child, but examination of the inheritable (blood-group) characters of the blood in relation to the supposed parents will in about one-third of the cases disprove the paternity of a particular man, for example a husband who is not really the father. Broadly speaking the child cannot have a group-character that it has not inherited from one or other parent. If all its group characters are accounted for in the blood of the husband and wife then the husband can (not necessarily must) be its father. Any character not possessed by one or other of the couple must, on the other hand, have come from a man not the husband. Small samples of blood are needed from husband, wife and child. Unfortunately since medico-legal blood grouping was discontinued at St Mary's Hospital, it has become very difficult to get the tests done in this country.

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Cost of Books

N E asks whether the cost of replacing old editions of medical books with new editions is an allowable expense.

*** *** It depends on the nature of the earnings from which the deduction of such expenses is claimed. If the earnings are assessable under schedule D (e.g., are derived from general practice) such expenses are normally allowable. If, however, the earnings are assessable under Schedule E (as are the emoluments of an employment) such expenses are disallowed on the ground that they are not incurred necessarily in the performance of the duties of the employment but rather to put the taxpayer into a position to perform them.

Letters and Notes

Blood Products for Transfusion by Ship Surgeons

The normal issue for each ship will be six bottles of dried plasma or serum together with sterile distilled water for reconstitution and two sterile giving sets. If this is considered insufficient, increased supplies may be made after consultation by writing or in person with the transfusion officer concerned, but no more than six bottles will be issued to an accredited messenger without such consultation. Any material not used within six months should be taken as so far as possible to the nearest depot for inspection. Supplies will not be available through shipping chemists. Further supplies will be issued against the return of the empty or unused bottles and giving sets to any of the undermentioned centres.

Gifts to Hospitals

The British Hospitals Association has prepared a memorandum which explains briefly how intending donors may still make gifts to hospitals with the assurance that their benefactions will be applied in accordance with their intentions and for the benefit of the particular hospital or locality in which they are interested. This object can be accomplished by taking care that the will, or deed of gift, or directions, make it clear that the gift is to be treated as a capital fund, separate from the general funds of the hospital, as a fund for some specific object of a capital nature. Such a gift may consist of money or of property. A point to be noted also is whether the gift is made before or after the "appointed day." Appropriate forms of words for use in making gifts to a hospital are included in the memorandum. These have been prepared by Chancery counsel at the request of the British Hospitals Association.

Buccal Ulceration and Menstruation

Dr A. G. T. Brown (Horley, Surrey) writes: "I noted the question (March 15 p. 365) put by a doctor concerning his edentulous patient who suffered from buccal ulceration near the time of menstruation and asking for the treatment. I saw a woman of the same name months ago with the same trouble who had had all dental work excluded. Stilboestrol gave her violent nausea but stopped the ulcers completely. In this case they were on the upper gum opposite the canine teeth. Subsequent trial with dienoestrol 0.3 mg. during the second half of the cycle taken every other day seemed to have prevented recurrence. Your correspondent may be interested in this treatment."

Correction

In our Epidemiological Notes of April 19 (p. 550) the statement "In Aberdeen 89 babies have died of gastro enteritis during the past three months" was incorrect. Over this period 89 was the total number of deaths of children under one year, of these deaths 31 were due to gastro enteritis.

SOME PROBLEMS IN THE TITRATION OF STREPTOMYCIN

BY

J R MAY, MB, BCh A E VOUREKA, MD

AND

ALEXANDER FLEMING, FRS

(From the Laboratories of the Inoculation Department St Mary's Hospital)

In the titration of an antibiotic substance it has been usual to choose for the test organism a microbe which is very sensitive and which is easy to work with. For streptomycin use has been made of Gram-negative bacilli such as *B. coli* or Friedlander's bacillus, and one strain of Friedlander's bacillus (*Klebsiella* 41) has been extensively employed in America. In this article we propose to deal with some of the difficulties we have encountered in the titration of streptomycin in solution or in the patient's serum. We might say here that, as we had no official standard solution of streptomycin, we used for these tests a standard solution made up by dissolving in 100 ml the contents of one bottle of Merck's streptomycin, which was labelled as containing 1 g of streptomycin hydrochloride.

Influence of the Nature of the Culture Medium

For some time we have been using glucose-phenol-red-serum water for the titration of penicillin in patients' serum. When streptomycin was titrated in this medium we found that we obtained a much higher end-point than when it was titrated in ordinary broth. We therefore made observations on the bacteriostatic power of streptomycin on a number of different organisms in four different media—namely, (a) ordinary digest broth, (b) peptone water, (c) glucose-phenol-red-serum water (this is made by boiling for a few minutes serum, 2 parts, distilled water, 6 parts, 10% glucose solution, 2 parts, and saturated solution of phenol red, sufficient to give a red colour), (d) defibrinated human blood, inactivated.

In regard to the first three media serial twofold dilutions of the stock streptomycin were made in the media which had been inoculated with 10 cmm per ml of a 24-hour culture of the test organism. This was done in 0.5 ml quantities in test-tubes. With broth and peptone water the end-point was the appearance of visible growth after 24 hours. In the serum water there was a colour change from red to yellow, and a precipitation of the medium where the organisms grew and fermented the glucose.

When the test was made in blood the streptomycin was diluted in saline in 25-cmm volumes, these were mixed with the same volume of blood which had been suitably infected with the test organism, and incubated in slide cells. As the growth of Friedlander's bacillus in blood is not very

obvious 2% glucose was added when testing this organism. When growth then occurred the blood was haemolysed and a good end-point obtained. The results are shown in Table I.

TABLE I—Bacteriostatic Power of Streptomycin tested in Different Media

Test Organism	Lowest Concentration (in Thousands) of Streptomycin Completely Inhibiting Growth in			
	Broth	Peptone Water	Glucose-Phenol-red-Serum Water	Human Blood Inactivated
Haemolytic streptococcus	1/100	No growth	1/2000	1/40
Staphylococcus	1/320	1/1600	1/4000	1/1000
<i>C. diphtheriae</i>	1/600	1/1600	1/4000	1/1000
<i>B. coli</i> (haemolytic)	1/40	1/160	1/1000	1/400
<i>Klebsiella</i> 41	1/320	1/500	1/4000	1/1000*
Friedlander 3	1/1500	1/4000	1/10 000	1/1000*

* A good end point was obtained only when 2% of glucose was added to the blood.

These results show that there is a great difference in the end-point according to the culture medium used. With one exception the lowest readings were obtained in broth, and invariably the highest readings were those in serum water. It is interesting that the results in human blood are usually considerably higher than in broth.

Influence of Dilution of the Culture Medium

In the first experiments streptomycin solution in distilled water was titrated in broth and in a tenfold dilution of this broth in distilled water. The titrations were done in 0.5 ml quantities in small test-tubes, and the end-point was the appearance of visible growth. The results are shown

TABLE II—Effect of Dilution of the Culture Medium with Water in the Titration of Streptomycin

Test Organism	Least Concentration Completely Inhibiting Growth of Test Organism in Broth	
	Undiluted	Tenfold Diluted
Staphylococcus	1/300 000	1/60 000 000
Haemolytic streptococcus	1/200 000	1/1 000 000
<i>C. diphtheriae</i>	1/600 000	1/60 000 000
<i>B. coli</i>	1/80 000	1/1 000 000
<i>Klebsiella</i> 41	1/300 000	1/100 000 000

in Table II. In this titration all the constituents of the broth were diluted. Another titration was done in broth and tenfold-diluted broth, to each of which glucose was added to make 2%. This gave the results shown in

TABLE III—Test Organism *Klebsiella 41* Growth in Dilutions of Streptomycin (in thousands)

	1/100	1/500	1/2500	1/12 500	1/62,500	Control
Broth + glucose	0	+	+	+	+	+
Tenfold-diluted broth + glucose	0	+	+	+	+	+

Table III. In both these experiments there was an enormous difference in the end-point in the diluted medium.

Meantime other experiments had shown that the salt content of the medium had some influence on the end-point, so titrations were made in broth, and in broth diluted ten times with water and with normal saline. The results

TABLE IV—Test Organism *Klebsiella 41* Growth in Dilutions of Streptomycin (in thousands)

	1/100	1/500	1/2500	1/12 500	1/62 500	Control
Broth undiluted	0	+	+	+	+	+
diluted in saline	0	+	+	+	+	+
in water	0	0	0	0	+	+

are shown in Table IV. This showed that the salt content of the medium made a considerable difference.

We made similar observations using serum water as the culture medium. The original serum water (serum 1 part boiled with 3 parts distilled water) was diluted with water and with saline, and to each was added 1% glucose and phenol red. The results appear in Table V.

TABLE V—Growth of *Klebsiella 41* in Serum Water diluted with Water and with Saline and containing Streptomycin as Under (in thousands)

	1/1600	1/3200	1/6400	1/12 800	1/25 600	1/51 200	1/100 000	Control
Serum water undiluted	0	0	0	+	+	+	+	+
Serum water diluted 10 times in saline 0.85%	0	0	+	+	+	+	+	+
Serum water diluted 10 times in water	0	0	0	0	0	0	+	+

The original serum-water medium has a much lower salt content than normal saline. (The only salt in it is that of the serum, which is diluted four times in water.) When this was diluted with water the titre of the streptomycin was much higher than in the undiluted serum water, but when it was diluted in normal saline it was slightly lower. When the salt content of undiluted serum water was raised to 0.85% it gave exactly the same end-point as did tenfold-diluted serum water with the same salinity.

These experiments confirm the statement which often appears in streptomycin literature, that the salt content is of considerable importance and that saline solutions to some extent inhibit streptomycin.

Effect of the Size of the Inoculum of the Test Organism

Experiments were made to see whether streptomycin behaves like penicillin, which gives the same end-point whatever the inoculum within quite wide limits, or like sulphadiazide, which is very sensitive to changes in the size of the inoculum. The same batch of medium (glucose-phenol-red-serum water) was divided into 4-ml volumes which were inoculated with 0.1 ml of serial dilutions of a

broth culture of the test organism (*Klebsiella 41*). Streptomycin solution 1 in 1,000,000 was titrated with each of these media, with the results shown in Table VI.

TABLE VI

Dilution of Broth Culture used as Inoculum	Growth resulting in Concentrations of Streptomycin (in millions)					
	1/2	1/4	1/8	1/16	1/32	Control
1/1	0	0	+	+	+	+
1/10	0	0	+	+	+	+
1/100	0	0	0	+	+	+
1/1000	0	0	0	+	+	+
1/10 000	0	0	0	0	+	+
1/100 000	0	0	0	0	+	+
1/1,000 000	0	0	0	0	+	+

It will be seen that there is a definite change in the end-point as the inoculum gets smaller. The titration is sensitive enough when the inoculum is considerable, as we have found that when very small inocula are used the results may be irregular. We have therefore used as routine an inoculum of 10 cmm of a 24-hour broth culture to each 1 ml of the culture medium.

Influence of Atmospheric Conditions

Experiments were conducted to see whether anaerobic conditions influenced the end-point. For the most part these were done in a very simple manner by making serial dilutions in 1-ml quantities in the infected culture medium and then transferring 0.5 ml to another set of tubes in which the fluid was covered with a layer of melted petroleum jelly. Thus we had one series of tubes fully exposed to the air and another exactly similar set from which air was excluded. It was found that with some of the organisms it required, in the absence of air, a higher concentration of streptomycin to inhibit growth completely.

TABLE VII—Influence of Anaerobic Conditions on the Titration of Streptomycin. Test Organism *Klebsiella 41* Medium: Glucose-Phenol-red-Serum Water

	Growths in Dilutions of Streptomycin Solutions				
	1/8	1/16	1/32	1/64	Control
Aerobic	0	0	0	+	+
Anaerobic	0	+	+	+	+

The same result was obtained when the anaerobic tubes were incubated (without the petroleum jelly covering) in an anaerobic jar.

Incubation in Capillary Tubes—In the past, when titrating penicillin in a patient's serum, we used small volumes and incubated in capillary tubes the serum dilutions with the test streptococcus and human blood. Later we used the same technique but diluted the serum in glucose-phenol-red-serum water. The capillary tubes were sealed in the flame and incubated horizontally stuck in "plasticine" on a microscope slide. When we adopted this last method with streptomycin, using *B. coli* or Friedlander's bacillus as the test organism, the end point was often obscured by the fact that in several tubes there was only a partial change of colour—one portion of the tube would be yellow and another red. We found also that the end-point was not the same as it was when the fluids were incubated in open tubes. We therefore compared the results obtained by incubating the same fluids in four different ways: (a) in 0.5-ml quantities in open test tubes; (b) in capillary tubes (about 1 in (2.5 cm) column of fluid); (b1) unsealed and incubated horizontally, (b2) sealed and incubated horizontally, (b3) sealed and incubated vertically.

TABLE VIII

Method of Incubation	Dilution of Streptomycin Solution				
	1/8	1/16	1/32	1/64	Control
Test tubes open	0	0	0	+	+
Capillaries open horizontal	0	0	0	+	+
closed horizontal	0	±	+	+	+
vertical	±	±	+	+	+

The results with open test-tubes and open capillaries were identical, but when the capillaries were sealed (in the flame) it required more streptomycin to inhibit growth and still more when they were incubated vertically. It seems possible that this may, in part at least, be due to the diminished access of air in the closed tube. This result was obtained with *B. coli* and Friedlander's bacillus and staphylococcus, but when streptococcus was used as the test organism the end-point was the same whether the capillaries were open or closed, and whether they were incubated horizontal or upright.

The fact that open capillaries gave what is apparently the true reading is fortunate in that it saves the time which would be occupied in sealing them. The capillaries used were about 4 in (10 cm) long and approximately 1 mm in diameter. When stuck horizontally in plasticine the fluid (unless there is rough handling) remains in place near the middle.

Sensitivity of Different Bacteria to Streptomycin

Many tables have been published giving the amount of streptomycin necessary to inhibit the growth of different bacteria. In a consideration of these figures we must take into account the medium in which the test was made, for, as we have seen, the nature of the culture medium makes a vast difference to the result.

TABLE IX—Sensitivity of Bacteria to Streptomycin in Broth and in Glucose-Phenol red-Serum Water

	No of Strain	Lowest Concentration Completely Inhibiting Growth			
		Broth		Serum Water	
		Lowest	Highest	Lowest	Highest
Friedlander's bacillus	5	1/30 000	1/1 500 000	1/2 000 000	1/12 000 000
<i>B. coli</i>	18	1/40 000	1/160 000	1/500 000	1/2 000 000
<i>Ps. pyocyanea</i>	5	1/20 000	1/40 000	1/1 000 000	1/4 000 000
<i>B. proteus</i>	6	1/10 000	1/20 000	1/500 000	1/2 000 000
<i>B. typhosus</i>	8	1/20 000	1/80 000	1/500 000	1/4 000 000
<i>B. paratyphosus A</i>	4	1/20 000	1/40 000	1/1 000 000	1/2 000 000
<i>B. paratyphosus B</i>	5	1/20 000	1/40 000	1/500 000	1/1 000 000
<i>B. paratyphosus C</i>	1	1/20 000		1/1 000 000	
Other Salmonella	6	1/20 000	1/160 000	1/500 000	1/2 000 000
<i>B. dysenteriae</i>	4	1/160 000	1/160 000	1/1 000 000	1/1 000 000
Haemolytic streptococcus	1	1/160 000		1/1 000 000	
<i>Streptococcus viridans</i>	7	1/50 000	1/400 000	1/1 000 000	1/6 000 000
Staphylococci	2	1/320 000	1/320 000	1/4 000 000	1/4 000 000
<i>H. influenzae</i> (Fildes extract added)	4	1/100 000	1/100 000	1/600 000	1/600 000

In Table IX we set forth the results obtained with a large number of organisms tested in our ordinary nutrient broth and in glucose-serum water. When figures are given as to the effect of streptomycin on bacteria it is quite obvious that the culture medium should be described, and it is also very desirable that a standard organism should be included in the test—such as the staphylococcus, which has been universally used for penicillin titration, or Friedlander's bacillus (*Klebsiella 41*).

Distribution of Streptomycin in Blood—Experiments were made to determine the relative amount of streptomycin in the corpuscles and the serum. A citation of one of these will serve.

Streptomycin 1/500 000 was added to serum. This was divided into two parts. One of these was mixed with an

equal volume of packed cells which had not previously been in contact with streptomycin. At intervals a sample of the mixture was centrifuged and the streptomycin content of the serum was compared with that of the control serum, to which no cells had been added. After one hour the bulk of the streptomycin remained in the serum and only a relatively small amount had passed into the corpuscles, but after six hours the streptomycin was equally distributed between the serum and the corpuscles.

Testing of a Patient's Serum for Streptomycin—As with penicillin it is desirable, in order to avoid undue bleeding of the patient, to use a micro-method, and the methods employed for penicillin are applicable to streptomycin, with a possible change of the test organism. Normal sera containing no streptomycin were tested by making dilutions in glucose-phenol-red-serum water infected with *B. coli* or Friedlander's bacillus, and it was found that growth was inhibited in the higher concentrations of serum. Sometimes it was only a 1 in 2 dilution which inhibited, but sometimes as much as 1/32 dilution showed no growth. When the serum was inactivated this bacteriostatic action disappeared. It follows from this that if this organism is used the serum must be inactivated, otherwise it will be impossible to detect small amounts of streptomycin in the serum.

Use of Liquoid for Inactivation—Inactivation of the serum by heat meant another operation, and we thought that by adding liquoid to the culture medium we might destroy the antibacterial power of the serum. Liquoid in a concentration of 1 in 2,000 did not interfere with the growth of any of the test organisms, and it completely destroyed the antibacterial power of the serum. We thought we had solved this problem until we discovered that liquoid interfered in some way with the action of streptomycin, as is shown in the following experiment (Table X). Different concentrations of liquoid were made in serum-water medium, and solutions of 1 in 200,000 streptomycin in the same concentration of liquoid were titrated in each of these media.

TABLE X

Concentration of Liquoid in Medium	Growth of Staphylococcus in Concentrations of Streptomycin (in thousands)						
	1/400	1/800	1/1600	1/3200	1/6400	1/12 800	Control
1/500	0	+	+	+	+	+	+
1/1000	0	0	±	+	+	+	+
1/2000	0	0	0	+	+	+	+
Control no liquoid	0	0	0	±	±	+	+

This interference of liquoid with streptomycin made it an unsuitable inactivating agent, and when using a test organism which is inhibited by human serum such serum has to be inactivated by heat before its streptomycin content is estimated. It was found that inactivation of the serum by heat (half an hour at 56° C) did not destroy the streptomycin.

The method of titrating streptomycin in blood serum which we have finally adopted is as follows.

1 Culture Medium—Serum 1 part, distilled water 4 parts boiled or steamed with 1% glucose and sufficient of a saturated watery solution of phenol red to give a very definite red colour. For use 1 ml of this medium is inoculated with 10 ml of a 24 hour broth culture of the test organism.

2 Test Organism—The Friedlander's bacillus (*Klebsiella 41*) which has been in use in America is very suitable, but if this is employed the patient's serum must be inactivated by heat before the test. Staphylococcus may be used (choosing a strain which is not inhibited by human serum). It is almost as sensitive as *Klebsiella 41* and there is no need to inactivate the serum. If the patient has had penicillin, staphylococcus cannot be used unless penicillinase is added to the medium.

in Table II. In this titration all the constituents of the broth were diluted. Another titration was done in broth and tenfold diluted broth, to each of which glucose was added to make 2%. This gave the results shown in

TABLE III—*Test Organism Klebsiella 41* Growth in Dilutions of Streptomycin (in thousands)

	1/100	1/500	1/2500	1/12 500	1/62 500	Control
Broth + glucose	0	+	+	+	+	+
Tenfold-diluted broth + glucose	0	+	+	+	+	+

Table III. In both these experiments there was an enormous difference in the end-point in the diluted medium.

Meantime other experiments had shown that the salt content of the medium had some influence on the end-point, so titrations were made in broth, and in broth diluted ten times with water and with normal saline. The results

TABLE IV—*Test Organism Klebsiella 41* Growth in Dilutions of Streptomycin (in thousands)

	1/100	1/500	1/2500	1/12 500	1/62 500	Control
Broth undiluted	0	+	+	+	+	+
diluted in saline	0	0	0	+	+	+
in water	0	0	0	0	+	+

are shown in Table IV. This showed that the salt content of the medium made a considerable difference.

We made similar observations using serum water as the culture medium. The original serum water (serum 1 part boiled with 3 parts distilled water) was diluted with water and with saline, and to each was added 1% glucose and phenol red. The results appear in Table V.

TABLE V—*Growth of Klebsiella 41* in Serum Water diluted with Water and with Saline and containing Streptomycin as Under (in thousands)

	1/1600	1/3200	1/6400	1/12 800	1/25 600	1/51 200	1/100 000	Control
Serum water undiluted	0	0	0	+	+	+	+	+
Serum water diluted 10 times in saline 0.85%	0	0	+	+	+	+	+	+
Serum water diluted 10 times in water	0	0	0	0	0	0	+	+

The original serum-water medium has a much lower salt content than normal saline. (The only salt in it is that of the serum, which is diluted four times in water.) When this was diluted with water the titre of the streptomycin was much higher than in the undiluted serum water, but when it was diluted in normal saline it was slightly lower. When the salt content of undiluted serum water was raised to 0.85% it gave exactly the same end-point as did tenfold-diluted serum water with the same salinity.

These experiments confirm the statement which often appears in streptomycin literature, that the salt content is of considerable importance and that saline solutions to some extent inhibit streptomycin.

Effect of the Size of the Inoculum of the Test Organism

Experiments were made to see whether streptomycin behaves like penicillin, which gives the same end-point whatever the inoculum within quite wide limits, or like sulphanilamide, which is very sensitive to changes in the size of the inoculum. The same batch of medium (glucose-phenol-red-serum water) was divided into 4-ml volumes which were inoculated with 0.1 ml of serial dilutions of a

broth culture of the test organism (*Klebsiella 41*). A streptomycin solution 1 in 1,000,000 was titrated with each of these media with the results shown in Table VI.

TABLE VI

Dilution of Broth Culture used as Inoculum	Growth resulting in Concentrations of Streptomycin (in millions)					
	1/2	1/4	1/8	1/16	1/32	Control
1/1	0	0	+	+	+	+
1/10	0	0	+	+	+	+
1/100	0	0	+	+	+	+
1/1000	0	0	0	+	+	+
1/10 000	0	0	0	0	+	+
1/100 000	0	0	0	0	+	+
1/1 000 000	0	0	0	0	+	+

It will be seen that there is a definite change in the end-point as the inoculum gets smaller. The titration is sensitive enough when the inoculum is considerable, as we have found that when very small inocula are used the results may be irregular. We have therefore used as routine an inoculum of 10 c.mm. of a 24-hour broth culture to each 1 ml. of the culture medium.

Influence of Atmospheric Conditions

Experiments were conducted to see whether anaerobic conditions influenced the end-point. For the most part these were done in a very simple manner by making serial dilutions in 1-ml quantities in the infected culture medium and then transferring 0.5 ml to another set of tubes in which the fluid was covered with a layer of melted petroleum jelly. Thus we had one series of tubes fully exposed to the air and another exactly similar set from which air was excluded. It was found that with some organisms it required, in the absence of air, a higher concentration of streptomycin to inhibit growth completely.

TABLE VII—*Influence of Anaerobic Conditions on the Titration of Streptomycin* Test Organism *Klebsiella 41* Medium 1 Glucose-Phenol red-Serum Water

	Growths in Dilutions of Streptomycin Solutions				
	1/8	1/16	1/32	1/64	Control
Aerobic	0	0	0	+	+
Anaerobic	0	+	+	+	+

The same result was obtained when the anaerobic tubes were incubated (without the petroleum jelly covering) in an anaerobic jar.

Incubation in Capillary Tubes—In the past, when titrating penicillin in a patient's serum, we used small volumes and incubated in capillary tubes the serum dilutions with the test streptococcus and human blood. Later we used the same technique but diluted the serum in glucose-phenol-red-serum water. The capillary tubes were sealed in the flame and incubated horizontally stuck to "plasticine" on a microscope slide. When we adopted this last method with streptomycin, using *B. coli* or Friedlander's bacillus as the test organism, the end point was often obscured by the fact that in several tubes there was only a partial change of colour—one portion of the tube would be yellow and another red. We found also that the end-point was not the same as it was when the fluids were incubated in open tubes. We therefore compared the results obtained by incubating the same fluids in four different ways: (a) in 0.5-ml quantities in open test tubes; (b) in capillary tubes (about 1 in 2.5 cm) column of fluid; (b1) unsealed and incubated horizontally, (b2) sealed and incubated horizontally, (b3) sealed and incubated vertically.

TABLE VIII

Method of Incubation	Dilution of Streptomycin Solution				
	1/8	1/16	1/32	1/64	Control
Test tubes open	0	0	0	+	+
Capillaries open	0	0	0	+	+
horizontal	0	±	+	+	+
closed	±	±	+	+	±
horizontal					
vertical					

The results with open test-tubes and open capillaries were identical, but when the capillaries were sealed (in the flame) it required more streptomycin to inhibit growth and still more when they were incubated vertically. It seems possible that this may, in part at least, be due to the diminished access of air in the closed tube. This result was obtained with *B. coli* and Friedlander's bacillus and staphylococcus, but when streptococcus was used as the test organism the end-point was the same whether the capillaries were open or closed, and whether they were incubated horizontal or upright.

The fact that open capillaries gave what is apparently the true reading is fortunate in that it saves the time which would be occupied in sealing them. The capillaries used were about 4 in (10 cm) long and approximately 1 mm in diameter. When stuck horizontally in plasticine the fluid (unless there is rough handling) remains in place near the middle.

Sensitivity of Different Bacteria to Streptomycin

Many tables have been published giving the amount of streptomycin necessary to inhibit the growth of different bacteria. In a consideration of these figures we must take into account the medium in which the test was made, for, as we have seen, the nature of the culture medium makes a vast difference to the result.

TABLE IX—Sensitivity of Bacteria to Streptomycin in Broth and in Glucose-Phenol red-Serum Water

	No of Strain	Lowest Concentration Completely Inhibiting Growth			
		Broth		Serum Water	
		Lowest	Highest	Lowest	Highest
Friedlander's bacillus	5	1/30 000	1/1 500 000	1/2 000 000	1/12 000 000
<i>B. coli</i>	18	1/40 000	1/160 000	1/500 000	1/2 000 000
<i>Ps. pyocyanea</i>	5	1/20 000	1/40 000	1/1 000 000	1/4 000 000
<i>B. proteus</i>	6	1/10 000	1/20 000	1/500 000	1/2 000 000
<i>B. typhosus</i>	8	1/20 000	1/80 000	1/500 000	1/2 000 000
<i>B. paratyphosus A</i>	4	1/20 000	1/40 000	1/1 000 000	1/2 000 000
<i>B. paratyphosus B</i>	5	1/20 000	1/40 000	1/1 000 000	1/2 000 000
<i>B. paratyphosus C</i>	1	1/20 000	1/40 000	1/1 000 000	1/2 000 000
Other Salmonella	6	1/20 000	1/160 000	1/1 000 000	1/2 000 000
<i>B. dysenteriae</i>	4	1/160 000	1/160 000	1/1 000 000	1/2 000 000
Haemolytic streptococcus	1	1/160 000	1/160 000	1/1 000 000	1/1 000 000
<i>Streptococcus viridans</i>	7	1/50 000	1/400 000	1/1 000 000	1/6 000 000
Staphylococci	2	1/320 000	1/320 000	1/4 000 000	1/4 000 000
<i>S. influenzae</i> (Fildes extract added)	4	1/100 000	1/100 000	1/600 000	1/600 000

In Table IX we set forth the results obtained with a large number of organisms tested in our ordinary nutrient broth and in glucose-serum water. When figures are given as to the effect of streptomycin on bacteria it is quite obvious that the culture medium should be described, and it is also very desirable that a standard organism should be included in the test—such as the staphylococcus, which has been universally used for penicillin titration, or Friedlander's bacillus (*Klebsiella* 41).

Distribution of Streptomycin in Blood—Experiments were made to determine the relative amount of streptomycin in the corpuscles and the serum. A citation of one of these will serve.

Streptomycin 1/500,000 was added to serum. This was divided into two parts. One of these was mixed with an

equal volume of packed cells which had not previously been in contact with streptomycin. At intervals a sample of the mixture was centrifuged and the streptomycin content of the serum was compared with that of the control serum, to which no cells had been added. After one hour the bulk of the streptomycin remained in the serum and only a relatively small amount had passed into the corpuscles, but after six hours the streptomycin was equally distributed between the serum and the corpuscles.

Testing of a Patient's Serum for Streptomycin—As with penicillin it is desirable, in order to avoid undue bleeding of the patient, to use a micro-method, and the methods employed for penicillin are applicable to streptomycin, with a possible change of the test organism. Normal sera containing no streptomycin were tested by making dilutions in glucose-phenol-red-serum water infected with *B. coli* or Friedlander's bacillus, and it was found that growth was inhibited in the higher concentrations of serum. Sometimes it was only a 1 in 2 dilution which inhibited, but sometimes as much as 1/32 dilution showed no growth. When the serum was inactivated this bacteriostatic action disappeared. It follows from this that if this organism is used the serum must be inactivated, otherwise it will be impossible to detect small amounts of streptomycin in the serum.

Use of Liquoid for Inactivation—Inactivation of the serum by heat meant another operation, and we thought that by adding liquoid to the culture medium we might destroy the antibacterial power of the serum. Liquoid in a concentration of 1 in 2,000 did not interfere with the growth of any of the test organisms, and it completely destroyed the antibacterial power of the serum. We thought we had solved this problem until we discovered that liquoid interfered in some way with the action of streptomycin, as is shown in the following experiment (Table X). Different concentrations of liquoid were made in serum-water medium, and solutions of 1 in 200,000 streptomycin in the same concentration of liquoid were titrated in each of these media.

TABLE X

Concentration of Liquoid in Medium	Growth of Staphylococcus in Concentrations of Streptomycin (in thousands)					
	1/400	1/800	1/1600	1/3200	1/6400	1/12 800
Control	+	+	+	+	+	+
1/500	0	+	+	+	+	+
1/1000	0	0	±	+	+	+
1/2000	0	0	0	±	+	+
Control no liquoid	0	0	0	0	±	+

This interference of liquoid with streptomycin made it an unsuitable inactivating agent, and when using a test organism which is inhibited by human serum such serum has to be inactivated by heat before its streptomycin content is estimated. It was found that inactivation of the serum by heat (half an hour at 56° C) did not destroy the streptomycin.

The method of titrating streptomycin in blood serum which we have finally adopted is as follows.

1 Culture Medium—Serum 1 part, distilled water 4 parts boiled or steamed with 1% glucose and sufficient of a saturated watery solution of phenol red to give a very definite red colour. For use 1 ml of this medium is inoculated with 10 ml of a 24-hour broth culture of the test organism.

2 Test Organism—The Friedlander's bacillus (*Klebsiella* 41) which has been in use in America is very suitable, but if this is employed the patient's serum must be inactivated by heat before the test. *Staphylococcus* may be used (choosing a strain which is not inhibited by human serum). It is almost as sensitive as *Klebsiella* 41 and there is no need to inactivate the serum. If the patient has had penicillin, *staphylococcus* cannot be used unless penicillinase is added to the medium.

3 Serial dilutions of the serum to be tested are made in normal saline solution, and to each of these dilutions is added an equal volume of the infected medium. We have preferred to use 0.25 ml volumes and carry out the incubation in capillary tubes open at both ends and stuck flat on plasticine on a microscope slide, but the test can be done in exactly the same way using larger volumes and incubating the mixtures in small test-tubes. When serum water is used as the medium for titration and *Klebsiella* 41 or *Staphylococcus* as the test organism the end point comes at a dilution of 1 in 4-6 million. In blood it requires about 1 in 1 million concentration of streptomycin to inhibit growth completely, so that this method will indicate a smaller amount of streptomycin than the therapeutic level, whereas if broth is used this would not be so. Serum water is also more suitable for the test as it is an unbuffered medium and the end point is more easily read than it is in broth.

4 Control—As the final end point of the titrations depends on so many factors it is necessary to make a control titration of a known concentration of streptomycin (1 in 1,000,000) in human serum. A comparison of the end point obtained with this and with the patient's serum will give an absolute measurement of the streptomycin content in the latter.

The accompanying Chart illustrates the result obtained by titrations of patients' serum following intramuscular

one volume of this mixture is taken with the same pipette and mixed in the same way with the second drop of diluent. But the pipette in making the first mixture has been wetted up to the second graduation mark, so that in making the second dilution the whole volume plus an additional wash is mixed with the volume minus a wash. This is an error accumulating with each of the serial dilutions, and while it is small with a short series it becomes serious when ten or more serial dilutions are made in this way. The extent of the error may be seen in the following experiment.

Dilutions of streptomycin were made accurately 1/10,000, 1/50,000, 1/1,000,000, and 1/5,000,000. These were titrated by twofold dilutions in glucose-phenol red-serum water infected with Friedlander 3. With 1/10,000 strength 14 serial dilutions were made before an end-point was reached. Complete inhibition of growth occurred in what purported to be 1 in 80,000,000 and growth occurred in 1 in 160,000,000. With the 1 in 50,000 strength 11 serial dilutions gave an end point of inhibition in 1/50,000,000 and growth in 1/100,000,000. With the 1/1,000,000 strength 5 dilutions showed inhibition in 1/16,000,000 and growth in 1/32,000,000. With the 1 in 5,000,000 strength 2 dilutions showed inhibition in 1/10,000,000 and growth in 1/20,000,000. A control series done by a method which eliminates the wash gave the same result as the last.

It is quite evident, therefore, that a long series of twofold dilutions made in the usual way by a method in which there is the cumulative error of the wash may give results which are wide of the mark. It is suggested that the series of dilutions made in this way should not exceed 5 or 6.

Fleming (1924) has suggested a method whereby dilutions can be made with capillary pipettes which avoids the error of the wash and can be adapted to the titration of streptomycin or other substance.

Summary

In the titration of streptomycin the end point depends on (1) culture medium, (2) atmospheric conditions, (3) nature of the test organism, and (4) size of inoculum of the test organism.

Results are given for many organisms in broth and serum water.

A method of titration of streptomycin in patients' serum is described.

Attention is drawn to an error inherent in the method of serial dilutions by capillary tubes.

Fleming, A (1924) *Brit J exp Path* 5 148

Chart showing the streptomycin content of a patient's serum after intramuscular injections of 0.33 g of the drug. The arrows represent time of injections.

injections of 0.33 g of streptomycin. Injections were given every four hours except that at bedtime that amount was doubled (indicated on the chart by a thick arrow), and eight hours elapsed before the next injection. The blood was tested just before each injection and at shorter intervals after the first and the sixth injections. It will be seen that at the end of the first injection interval there were still 2 units per ml in the serum, but after three injections the residual amount was maintained at 4 to 5 units.

ADDENDUM

Error in making Serial Dilutions with a Capillary Pipette

The usual method is to lay out on a paraffined slide a number of equal volumes from a graduated capillary pipette. None of these is the whole volume represented by the graduation, all of them are that volume less the wash of fluid which wets the inside of the pipette. This varies with the bore of the pipette and with the rate of expulsion, but Fleming (1924) estimated that with ordinary capillary pipettes and at the normal rate of working the wash amounted to about 3%.

The fluid to be diluted is taken up to the graduation mark in the pipette, expelled into the first drop of the diluent, and then mixed by sucking up and expelling the fluid several times. This means that the whole of the fluid to be diluted is mixed with the same volume of the diluent minus the wash. Then

The Royal Sanitary Institute will hold its 1947 health congress at Torquay, from June 2 to 6, at the invitation of the Corporation. The Earl Fortescue, Lord Lieutenant of the County of Devon, will be President of the Congress. The following is a selection from the provisional programme: June 2, 3 p.m., official welcome by the Mayor of Torquay and inaugural address by the president of the congress. June 3, 10 a.m., Section of Preventive Medicine, discussions on 'The Scope of Public Health after 1948' and 'The Present Position and Prospects in Whooping-cough Immunization'. Section of Engineering and Architecture, discussions on 'The Design and Location of Health Centres' and 'Engineering Standards in Relation to Health'. Sanitary Inspectors conference, discussions on 'The Social Aspect of the Housing Problem' and 'Milk: A Food for Thought'. June 4, 10 a.m., Medical Officers of Health conference, discussion on 'The National Health Service Act and the Public Health Service'. Health Visitors conference, discussion on 'The Expanding Duties of the Family Health Team'. June 5, 10 a.m., Section of Maternal and Child Health, discussion on 'Infantile Mortality: The Clinical Aspects'. Section of Tropical Hygiene discussion on 'The Practical Application of Recent Advances in Tropical Medicine and Hygiene in Rural Tropical Areas', (a) Anopheles (Malaria) Eradication in Karpas, Cyprus 1946, and (b) Native Welfare in its Wider Aspects, including Nutrition and Housing. June 6, 10 a.m., Section of Maternal and Child Health, discussion on 'Infantile Mortality: The Preventive Aspects'. Section of Veterinary Hygiene, discussion on 'The Importance of Cowshed Hygiene in the Transmission of Milk-borne Diseases'. Section of Food and Nutrition, in conjunction with the Food Group of the Society of Chemical Industry, discussion on 'The Microbiological Aspects of Food Quality'.

THE PHYSICAL HEALTH OF CHILDREN ATTENDING DAY NURSERIES

A REPORT TO THE DAY NURSERIES COMMITTEE
OF THE MEDICAL WOMEN'S FEDERATION

BY

MARGARET E McLAUGHLIN, MB, BS, DCH

PART II

6 Postural and Foot Conditions

Comparison was made between the home and nursery groups of the incidence of poor posture, genu valgum, and pes valgus in children over 2 years of age. Under 2 years a comparison was felt to be useless owing to the normal variation in time of walking and of development of the arches of the foot. (a) *Poor posture* included lordosis, round shoulders, stooping, and hyperextension or sagging of the knees on standing, (b) *Genu valgum* was recorded where the gap between the internal malleoli was over 1/2 in (1.25 cm) in the supine position, (c) *Pes valgus* included not only advanced flat foot but also those cases where the child habitually walked and stood on the inner border of the foot.

Results (Tables VIII IX X)—Poor Posture—A slightly higher incidence was recorded in the nursery group for all ages together (2-5) and in individual age groups, but no difference was significant except in boys of 2-5 years. **Genu valgum**—At all ages together (2-5) and in all individual age groups, there was a slightly higher incidence in the nurseries except among boys of 2-3 years, where the home group had a slightly higher rate. No differences were statistically significant except in girls of 2-3 years, where the nursery rate was significantly higher. **Pes valgus**—The nursery rate was higher throughout, and all differences were significant except among girls and boys of 4-5 years. Pes valgus was about two and a half times more frequent among nursery boys and three times more frequent among nursery girls than in the corresponding home groups.

TABLE VIII—Percentage of Examinations where Poor Posture was found

* Significant differences

from 0 to 5 years of age. The results for boys and girls are given separately.

Results—(a) Boys—The mean weight of boys in the home group was greater than in the nursery group up to 2 years old, the difference being significant in four out of seven groups. Over 2 years the nursery boys had a greater mean weight in every age group, the difference being significant in three out of 12 groups (between 2 and 3 years). **(b) Girls**—Among the girls under 2 years the mean weight was greater in the home group in six out of eight age groups, the difference being significant in four of these groups (all under 18 months). Over 2 years the nursery girls had a greater mean weight in 11 out of 12 age groups, the differences not being significant in any age group.

The children in the nursery group therefore were on an average lighter under 2 years.

gained weight more rapidly between 1½ and 3 years, but up to 1½ years and over 3 years the rate of weight gain was closely similar in both groups

Sex Differences

At all ages over 6 months in both groups the boys showed a slightly greater mean weight than the girls. The general condition of boys was also on the whole very slightly better than that of girls, though this was not found in every age group. This finding was the same for nursery and home groups. In every other physical finding relating to tonsils, cervical glands, respiratory infections, and postural conditions in both groups the girls had a slightly better record. The difference between boys and girls was not more marked in one group than in the other.

Seasonal Variations in Physical Condition

The seasonal variations in physical condition were closely similar in nursery and home groups, but throughout the year the incidence of all cervical gland enlargements, of tonsillar enlargement, and of chronic nasopharyngeal infections was about 2 to 4 times greater in the nursery group.

Incidence of Specific Infectious Fevers

At each examination a full history was taken of any infection contracted since the previous examination of that child. Only definite accounts of infections were recorded, doubtful instances where evidence was insufficient being excluded. It is probable, therefore, that the figures given below represent somewhat less than the actual total occurrence. Accounts of "diarrhoea," "pneumonia," and certain other infections have been omitted, since these terms cover such a wide range of variable illnesses. In the case of pneumonia particularly, the early use of sulphonamides has made it unlikely that a record of pneumonia on hearsay account would be reliable. For similar reasons accounts of infections of the respiratory tract have been excluded, unless seen also at the time of examination. The incidence of measles, pertussis, varicella, and mumps has been compared, and of these only measles developed often enough for a detailed study of the incidence.

It will be clear that the total incidence of infectious diseases refers to a period of rather less than 11 months, since no account could be taken of infections occurring at the extreme beginning or end of the survey, before a child's first visit or after the last visit. Likewise the figures are based only on those children attending more than once—432 in the nursery group and 409 in the home group.

(a) The total incidence of varicella, mumps and pertussis (Table XII) was very low in both groups, varicella and

TABLE XII—Total Incidence of Infectious Fevers during Survey (November–October)

	No under Observation	Measles	Pertussis	Varicella	Mumps
Nursery group	432	111	11	14	9
Home group	409	33	18	7	2

mumps being slightly more numerous in the nursery group and pertussis in the home group. Over 80% of the children in both groups gave no history of a previous attack of any of these three fevers. Some children in the nursery group had received prophylactic injections against pertussis; this was extremely rare in the home group.

(b) Measles (Tables XIII and XIV)—Measles was present in epidemic form in Birmingham during the winter period of the investigation.

1 The total recorded incidence of measles in the nursery group during the survey was 111 out of 432 children. This

TABLE XIV—Age Distribution of Measles (Percentage distribution of all cases recorded during survey)

		All Ages 0–5 yrs	Under 18 mths	18 mths –3 yrs	3–5 yrs
(a) Age Distribution based on Total Population Observed					
Nursery group	No under observation	432	123	152	157
	Cases of measles	111	36	45	30
	% developing measles	25.7%	29.2%	29.6%	19.2%
Home group	No under observation	409	148	150	111
	Cases of measles	33	7	17	9
	% developing measles	8.1%	4.7%	11.3%	8.1%
(b) Age Distribution based on Presumed Susceptibles only					
Nursery group	No of presumed susceptibles	274	107	94	73
	Cases of measles	111	36	45	30
	% developing measles	40.5%	33.6%	47.9%	41.0%
Home group	No of presumed susceptibles	328	139	120	69
	Cases of measles	33	7	17	9
	% developing measles	10.0%	5.0%	14.2%	13.0%

was considerably higher than in the home group—33 out of 409—the difference being statistically significant. The percentage incidence during the period was 25.7 in the nursery group and 8.1 in the home group. There was a marked difference in the percentage of those who had already had measles, the proportion being significantly higher in the nursery group. These may be termed 'presumably immune,' and the others who had not had measles before the survey began may be termed 'presumably susceptible.' The presumably susceptible were 63.4% in the nursery group and 80.2% in the home group. If the total incidence be expressed as a percentage of the presumed susceptible, then 40.5% developed measles in the nursery group during the survey compared with 10% in the home group. These differences are statistically significant and are striking. The closer daily contact of children in nurseries naturally encourages greater spread of infection, and probably accounts in large measure for this difference in incidence.

2 The Age Distribution of Measles—At all ages (0–5 years) the recorded percentage incidence of measles was markedly higher in the nurseries group than in the home group. Among all children from 0–18 months old the percentage incidence of measles was more than 6 times greater in the nurseries group than in the home group. Between 18 months and 3 years of age and between 3 and 5 years the percentage incidence of measles was about two and a half times heavier in the nursery group than in the home group. In the nurseries group the percentage of children under 18 months old who developed measles during the survey (29.2%) was greater than the percentage incidence for all ages (25.7%), whereas in the home group the percentage of children under 18 months old who developed measles during the survey (4.7%) was little over half the percentage incidence for all ages (8.1%). Among those children who had no previous history of an attack of measles—the presumed susceptibles in each group—the proportion who developed measles during the survey in the nurseries group was 40.5% and in the home group only 10%, for all ages (0–5 years). Of those under 18 months old, 33.6% of the presumed susceptibles in the nurseries group developed measles during the survey, compared with 5% in the home group. These results show that the higher incidence of measles in the nursery group affected children of all ages up to 5 years but especially those under 18 months old. Thus the nursery children not only were much more likely to develop measles but tended to develop it at an earlier age than the home

children. This is particularly important in view of the greater mortality rate of measles in young infants and the greater risk of serious complications.

3 Seasonal Variations—In each of the six winter months of the survey (November–April) an average of 8.9% of the mean population under observation per month developed measles in the nursery group compared with 2.5% in the home group. In the six summer months (May to October), the incidence of measles per month in the nursery group was 0.05% of the mean population under observation in each month, compared with 0.2% in the home group. Thus measles was more evenly spread over the year in the home group, whereas the nursery group had a higher epidemic incidence in the winter, followed by a very low summer rate—a noteworthy difference when the increased mortality rate of measles during epidemics is considered.

Conclusions and Discussion

The main results of the survey may be summarized as follows:

1 The average weight of children under 2 years of age attending day nurseries was consistently less than that of the children living in their own homes, but from 2 years onwards the average weight of nursery children increased more rapidly and finally exceeded that of the home group of children.

2 The general condition as recorded from the clinical impression, was inferior in nursery children under 2 years old to that of children of the same age living in their own homes.

3 The incidence of respiratory tract infections, including acute and subacute infections present at examination and chronic conditions such as mouth-breathing and chronic tonsillar and cervical gland enlargements, was from two to eight times greater in the nursery children than among those living at home. This excess was manifest at all ages and in every season.

4 A significantly higher incidence of specific infectious fevers occurred in the nursery group, and the epidemic occurrence of measles was more marked than in the home group. Among those children "presumed susceptible" in the nursery group, the incidence of measles was four times greater than in those "presumed susceptible" in the home group.

5 Poor posture, genu valgum and pes valgus occurred more often in the nursery group than in the home group.

Before conclusions are drawn from the above findings it must be stated that this survey was confined to an investigation only of the physical health of the children, and no attempt has been made to assess the effect of nursery life on the child's psychological development or well-being.

The above findings are closely similar as regards respiratory tract infections and weights to those of the recent report of the Day Nurseries Committee of the Medical Women's Federation on the health of children in day nurseries. That report was based on the results of a single restricted examination of a large number of children (4,587) by many workers in many parts of the country, thus attaining a "cross-section" result, whereas the results of the present survey have been obtained by repeated, more detailed examinations over a period of one year by a single worker of a small group of children (1,198) in a single town and these results include also data on specific infections, fevers, postural conditions, etc.

In the report referred to above the physical condition of children seen within one week of admission to a nursery was assessed separately in order to determine whether there were any significant physical differences between welfare-centre children and nursery children at the start of nursery life. Statistical interpretation of these findings showed that the high rate of respiratory tract infections in day-nursery children could not be accounted for on these grounds. The inference that there were no significant physical differences at the start of nursery life between day-nursery children and

those living at home may reasonably be assumed to apply also to the present survey.

Only Ministry of Health wartime day nurseries were included in this survey, comparable results would, however, be likely in any similar aggregation of young children such as in nursery schools and classes, though it must be remembered that children of the youngest age groups do not attend nursery schools.

It was hoped to include in this survey a comparison of the incidence of infections in those nurseries housed in adapted private or other dwellings and those in specially constructed one-story buildings, the children of which spent a considerable amount of time out of doors. However, the numbers available for comparison between these two types of nurseries in similar social and economic areas were too small to be of statistical value. Conflicting opinions exist on this point, but the impression gained during the survey was that in the one-story "Mayerete"-type of nursery buildings there was a lower incidence of respiratory and other epidemic infections, associated probably with the free ventilation and the extra time spent by the children in the open air.

The superiority in weight of the older day-nursery children over the home group may be correlated with the more generous diet available to them under wartime arrangements. In this survey the nursery children under 1½ years showed a rise in average weight equal to that in the home group, and a more rapid rise in average weight than the home group from 1½ years of age. This more rapid rise in the nursery group continued until 3 years, and after this the rate of weight gain was practically the same in each group, with the nursery group having a higher average weight than the home group, although under 1½ years it had been lower. Nursery children were in fact gaining weight more rapidly from the age of 1½ years. This is roughly equivalent to the time at which the more liberal diet available to children attending day nurseries might be expected to begin to take effect. The improvement in general condition as recorded from clinical impressions followed a similar pattern, though differences between the older nursery and the home children were not statistically significant. It would be interesting to study the effect on both weight and general condition of allowing a similar extra amount of rationed food to children living in their own homes.

The increased weight and better physique of the older day-nursery children did not apparently influence their liability to infections of the respiratory tract. The findings in this investigation endorse the view that when children under 5 years of age are congregated together indoors for long periods a great increase in respiratory and other infections will occur, in spite of careful measures taken in the management of the day nurseries to minimize the spread of infection. It is realized, of course, that wartime staff shortages and use of adapted premises have created difficulties, and that under ideal conditions with generous staffing with trained personnel and ideal buildings the infection rate might be considerably less but these conditions are not likely to be achieved on a large scale.

The signs of fatigue noted in the nursery group in the higher incidence of pes valgus may be associated with the long hours kept by the nursery children, who were frequently and inevitably up for 13 to 14 hours daily while their mothers were on full-time work. These long hours were a special feature of an emergency period and should not continue.

The much higher incidence of respiratory and other infections and the increased liability to epidemic infections which, according to the evidence, is associated with nursery

life must be an important factor when a large-scale future provision of day nurseries is considered. Short of ideal conditions (and the economic possibility of attaining these is remote), a large amount of respiratory infection, with the usual aftermath of ill-health and complications, may be expected, and must be balanced against the possible advantages of communal life for young children. The possibility exists that the risk of respiratory infections might be reduced considerably by part-time attendance at day nurseries, and the incidence of respiratory infections in children attending nurseries for two or three half-days a week is a question worthy of investigation.

Reference must be made to other work on this subject published since this survey was begun. The report by the Day Nurseries Committee of the Medical Women's Federation (1946) on the health of children in day nurseries revealed a higher rate of respiratory infections in children attending day nurseries than in those living at home, and showed evidence that "for children under 2 years old nursery life had an adverse effect on physical health."

In a study of infections in wartime day nurseries in Oxford (Allen-Williams, 1945) routine health records of children in day nurseries and attending welfare centres were analysed, and it was deduced that there was a greater liability to infections among nursery children, and that these infections occurred at an earlier age, than among children living at home. The records of infections and other details were, however, admittedly incomplete.

A study of the progress of children under 2 years of age in day nurseries in Leyton (Menziès, 1946) concluded that "a substantial proportion of children under 2 years old do not make satisfactory progress on admission to a nursery, as judged by the weight gain", in spite of the very liberal diet in the nurseries, and drew attention to the importance of including in a survey of the health of children in day nurseries those who leave after a relatively short time of attendance because of "fretting" or contracting an infection.

Summary

An investigation in the health of children attending wartime day nurseries was carried out in Birmingham in 1944-5. During a period of one year repeated examinations were made by a single examiner of 557 children attending day nurseries and of a control group of 641 children living at home.

The results are based on a total of 3,250 examinations of children from 0-5 years old.

1 Respiratory tract infections were from two to eight times more frequent among nursery children than among the home group. This excess was manifest at all ages and at every season.

2 The incidence of measles was significantly higher in the day-nursery group, and was four times greater among those presumed susceptible in the day nurseries than in the home group. This excess was marked at all ages, but affected particularly those under 18 months old. The epidemic occurrence of measles was more pronounced in the nursery group than in the home group. These findings are important in view of the increased mortality from measles under 18 months of age and during an epidemic.

3 Pes valgus was more than twice as common among day-nursery children as in those living at home. The significance of this as a sign of fatigue is discussed.

4 Children over 2 years of age attending day nurseries were heavier than the children living at home, and they gained weight more rapidly between 1½ and 3 years of age. This may be correlated with the extra allowances of rationed foods (meat, bacon, cheese, eggs, etc.) available under the rationing system to children in day nurseries.

This investigation was made possible through the generosity of a donor who wishes to remain anonymous. Grateful acknowledgments are made to Dr W J Martin for his statistical assistance, and to Dr Newsholme and Dr Jean MacKintosh, of Birmingham

Public Health Department, for kindly providing facilities for the survey. Lastly, many thanks are due to the staffs of the nurseries and welfare centres, for whom this survey involved much extra work for their enthusiastic help and co-operation throughout.

DE MORGAN'S SPOTS

BY

A R MURISON J W SUTHERLAND
Captain R A M C Lieutenant R A M C

AND

A M WILLIAMSON
Flying Officer R A F

The minute round ruby-coloured macules known as De Morgan's spots are of common occurrence in adults. They are most often seen in the skin of the abdominal wall. They vary in size up to a diameter of about 5 mm and in number up to 20 or occasionally more. Microscopically they have the character of simple haemangiomas.

The spots are named after Campbell De Morgan, surgeon to the Middlesex Hospital from 1842 to 1875. Tradition holds that De Morgan believed the spots to indicate or presage malignant disease, particularly of the stomach. If this was his view he did not (so far as we have been able to discover) commit it to paper. In his book *On the Origin of Cancer* (1872) he does indeed mention the spots, but only as the merest aside. In the course of developing the argument that cancer is not due to an infective agent he says (p 16) "I have noticed, and it has been verified by the observation of others, that concurrently with, or following on, the development of cancer, small outgrowths of warty or vascular or dermoid structure are frequent. Now one would imagine that, if there were a cancer poison in the blood, these or one of them would become the seat of the disease. But—" And he makes no further reference to the spots which are now known by his name.

The literature on the ruby spots is extremely meagre, and the only paper of note is Sampson Handley's in 1909. He points out that the spots are found in atrophic skin, and begin as small nodules of connective tissue under the epidermis. As the spots enlarge, wide blood channels make their appearance and by their bulk elevate the epidermis, causing further atrophy. He draws attention to the common belief that the spots occur more often in patients affected with cancer, but emphasizes that this belief lacks corroboration. From this brief review of previous work it will be clear that, although the ruby spots by virtue of their brilliant appearance often arouse comment and keen though transitory interest, there is an entire absence of precise information on their significance. Accordingly, it seemed to us useful to collect data over a series of cases large enough to demonstrate their frequency and incidence.

Frequency and Incidence of Spots

Method of Investigation—The greater part of this paper is based on observations made on 1,300 patients at three Glasgow hospitals—the Western Infirmary, Stobhill Hospital, and the Radium Institute. The routine adopted was to visit in turn each of the general medical and surgical wards and to make observations on every patient available for examination. The area of skin examined for spots extended from the nipple line to the pubis, and laterally as far as the mid-axillary lines. This area was chosen for

convenience and because it is much the commonest site of the spots. For each patient a record card was prepared giving the age, sex, and provisional diagnosis, as well as information about the spots. The spots were classified into groups according to their diameter (as measured by a simple celluloid template), and the number of spots in each size group was noted.

The observations here presented were made in 1944, during our term of office as house-surgeons in the Western Infirmary, Glasgow. Since then one of us has been able to observe at routine medical inspections a large number of healthy men and women of the R.A.F. and W.A.A.F., and the opportunity has been taken of recording (though in less detail) the presence or absence of ruby spots. These observations are contrasted with those made in hospital. It has to be stated explicitly that none of the patients or Service personnel was chosen for record because of the presence or absence of ruby spots.

Influence of Age on Incidence—Since, as Sampson Handley pointed out, the spots rarely occur before middle life, it is clear that an apparently high incidence of spots in patients with cancer (who are nearly all elderly) might well be fallacious. Accordingly, before proceeding to other considerations it is necessary to determine the relationship of age to the incidence of spots. In Fig 1 we have included all Glasgow patients, male and female, cancerous and non-cancerous, and analysed the figures according to the number of patients with spots in each age group. It will be seen that the proportion of patients with spots rises progressively with age, at all events up to the age of 70. Thus in adolescence some 5% of patients have spots, but thereafter the proportion increases throughout adult life till in old age about 75% have spots. It is

FIG 1—Age incidence of De Morgan's spots (three hospitals, both sexes)

thus quite clear that the number of patients with spots in any series will vary greatly with the ages of the patients considered, and it will therefore be essential to make comparisons at each age group separately when comparing one series with another.

Frequency in Hospital Patients as Compared with Air Force Personnel—A comparison of the frequency of spots in hospital patients and in Air Force personnel is shown in Fig 2. It will be seen at a glance that, age for age, the proportion of individuals with spots among the Air Force personnel was much less than among the patients. Analysis confirms that the discrepancy is too great to be readily attributed to chance, and some other explanation must be sought. What the explanation may be is open to speculation, for the two series differ in many respects—in race, in health, in sex composition, and doubtless in other ways. It should be noted that the Air Force personnel

FIG 2—Incidence of De Morgan's spots in hospital patients and Air Force personnel

were in the main English, whereas the patients were drawn from the West of Scotland. The possibility of a racial difference in the incidence of spots is attractive and merits

further study. On the other hand, we are inclined to think that differences in sex composition and in health are probably not important. The evidence on which we base this opinion is given below.

Sex incidence—For the purpose of discovering if there was any sex difference in the incidence of ruby spots, we combined all patients from the Western Infirmary and Stobhill Hospital, and classified them (irrespective of disease) according to sex and the presence or absence of spots. It will be seen from Fig 3 that the frequency of patients with spots (age for age) is almost the same in males and females, and analysis confirms that any small differences are readily attributable to the chances of sampling.

FIG 3—Sex incidence of De Morgan's spots (two hospitals, all diseases)

Influence of Disease on Incidence of Spots

In order to find out if there was any such influence we divided our patients into three broad categories: *Group 1* patients without systemic disease (e.g., fracture cases) and those with acute disease (e.g., pneumonia); *Group 2* patients with chronic disease (e.g., tuberculosis); *Group 3* patients with malignant disease. A comparison of the incidence of ruby spots in "acute disease" and in "chronic disease" was made by combining the patients from the Western Infirmary and Stobhill Hospital (irrespective of sex) and classifying them according to the presence or absence of spots. It will be seen from Fig 4 that the frequency is almost the same, analysis confirms that the small discrepancies are readily attributable to the chances of sampling.

FIG 4—Incidence of De Morgan's spots in acute and chronic disease (two hospitals, both sexes)

A comparison of the incidence of ruby spots in malignant disease as against the incidence in all other diseases combined was made by pooling all patients (irrespective of sex) from the three hospitals and classifying them according to the presence or absence of spots. Fig 5 shows that in malignant disease the frequency of patients with spots was a little higher than that in non-malignant disease at all ages. It should, however, be noted that the differences are small, except at age 31–40 years (where the group of malignant cases comprises only 15 patients). Indeed, analysis reveals that a total discrepancy of the magnitude found might be expected to arise through the chances of sampling about once in eight such experiments, and the differences found cannot therefore be regarded as important. The very fact that a series consisting of 160 malignant and 784 non-malignant cases is insufficient to establish a significant difference in the incidence of ruby spots indicates clearly that the presence or absence of spots has no diagnostic importance.

FIG 5—Incidence of De Morgan's spots in malignant and non-malignant disease (Western Infirmary, Stobhill Hospital, and Radium Institute, sexes combined)

The somewhat unlikely possibility that cancerous patients might have spots which were unusually numerous or unusually large was investigated by comparing the malignant and non-malignant series, and no significant differences were found.

Increase in Number and Size of Ruby Spots with Age

Hitherto we have restricted attention to the question whether ruby spots were present or absent. It remains to describe how they increase in number and size as age advances, and to attempt an estimate of their rate of growth. For this purpose it has seemed best to pool all the information available from the three Glasgow hospitals. Among the data recorded for each patient was a count of the number of spots of diameter less than 1 mm, between 1 and 3 mm, and over 3 mm. The number of spots of each size (per 100 patients) was therefore easy to determine for each age group. These estimates are illustrated in Fig 6.

FIG 6—Influence of age on number and size of De Morgan's spots

It will be seen that the total number of spots per 100 patients (represented by the top line in Fig 6) increases at first slowly from zero at age 0-10 years to about 50 at age 21-30, and then increases rapidly to close on 500 at age 61-70, thereafter there is no increase. Again, it will be observed that the size of the spots, as well as the total number, increases with advancing age. Thus under the age of 30 years the majority of the spots are small (less than 1 mm in diameter). Thereafter as age advances there is an ever-increasing proportion of spots of medium size (between 1 and 3 mm in diameter). The proportion of large spots (over 3 mm in diameter) also increases with age, but they never become very numerous: thus at age 21-30 years they account for about one-tenth of the whole, whereas in old age they account for about one-fifth of the whole.

The data already given (Fig 6) can be made the basis of a rough estimate of the average rate of growth of the ruby spots. The estimate was made as follows:

Fig 6 shows reasonably smooth sequences except at age 61-70 years, and the values given were therefore used direct except that at this age the total count was arbitrarily reduced (at the expense of spots of medium size) from 481 to 430. The average number of years taken by the spots to attain a given diameter was then read off from the graph by a method best explained by illustration. Thus at age 36 (the mid value of the decade 31-40) there was a total of 183 spots per 100 patients, of which 93 measured 1 mm or more in diameter and the

remainder were smaller. It was assumed that the larger spots had been present longer than the smaller spots. But a total count of 93 spots was present (reading from the graph) at age 29 years. It was inferred that the spots which measured 1 mm or more at age 36 had been present for at least seven years. Using this method the following estimates of the average time taken by ruby spots to attain a given diameter at various ages were obtained:

Age in years	No. of years required to attain a diameter of	
	1 mm	3 mm
6	—	—
16	6	—
26	9	17
36	7	22
46	12	28
56	13	30
66	13	38
76	22	47

A high degree of precision cannot be claimed for these estimates, but the general statement can be made that the rate of growth of ruby spots decreases as age advances. Thus to attain a diameter of 1 mm the spots require about seven years in early adult life, and about twice or thrice this period as age advances. Similarly, to attain a diameter of 3 mm the spots require about 20 years in middle age, and about double this period in old age.

Summary

The literature of De Morgan's spots is reviewed and their possible connexion with cancer discussed.

Data on the incidence of ruby spots were obtained from observations on 1,300 patients at three Glasgow hospitals.

No difference was found in sex-incidence.

The proportion of hospital patients with ruby spots rises from 5% in adolescence to about 75% at 70 years of age. The spots also increased in number and size with advancing age, but their rate of growth decreased.

The proportion of Air Force personnel with spots was found to be much less than that of the hospital patients.

De Morgan's spots were slightly commoner in malignant than in non-malignant disease, but not sufficiently so to be of diagnostic importance.

The observations recorded here were made for the most part during our terms as house surgeons under Prof. Illingworth in the Western Infirmary, Glasgow. We are indebted to the physicians and surgeons in charge and to the medical superintendents of the Western Infirmary, Stobhill Hospital, and the Radium Institute for permission to examine their patients. Our particular thanks are due to Mr R. A. Jameson for his help in preparing this paper and in the statistical analysis, and to Dr R. A. Robb, of the Mathematics Department of Glasgow University, for suggesting the method of estimating the rates of growth. We have to acknowledge our indebtedness to the Air Ministry for permission to publish the data referring to Air Force personnel.

Gleneagles Hotel taken over for hospital purposes in 1939 by the Department of Health for Scotland, and since 1943 used as a fitness centre for the rehabilitation of miners, is being returned to the LMS Railway Company. The Centre reopened at Bridge of Earn Hospital, Perthshire, on April 28, where its facilities will be extended by association with the work of a general hospital. Although originally miners only were accepted, any person in industry may now be admitted to the Centre if suffering from a disability which may yield to treatment. Patients can be admitted on application to the Medical Superintendent by their family doctor or the medical officer of a hospital. The Consultative Committee appointed by the Secretary of State for Scotland in 1943 to advise on the Centre is being reconstituted under the chairmanship of Sir Robert Nimmo. The Committee will now include representatives of the National Coal Board, the mining industry, employers and workers in industry generally, and the British Medical Association.

RELAPSING FEVER IN CYRENAICA

BY

N F COGHILL, MA, MB, MRCP
*Late Major, R.A.M.C. Medical Specialist*J LAWRENCE, MRCS, LRCP
Late Captain R.A.M.C. Graded Physician

AND

I D BALLANTINE, MB, ChB
Late Captain R.A.M.C.

The objects of this paper are to describe four cases of relapsing fever seen in Cyrenaica, one of which was contracted in Benghazi, to discuss the relevant literature, and to bring to light some new information (not our own) regarding vectors of relapsing fever in Cyrenaica.

The pre-war Italian work on the disease in this area is worth noting. Vernoni¹ was the first to describe a case of relapsing fever with positive blood film, this occurred in Barce (El Merg). Medulla has contributed a number of articles on the subject. In 1931 he drew attention to various types of recurrent fevers in Cyrenaica, most of which, however, had negative blood films.² In 1933 he described two cases, confirmed microscopically, which may have been infected in Benghazi,³ and in 1934 he reported a further four cases which were infected while on military manoeuvres in the Jebel, near Cyrene, only two of these appear to have had positive blood films.⁴ In 1935 he published three more cases from the same source, in only one of which were spirochaetes seen in the blood.⁵ In the same year he described a further well-proved case from Apollonia, in this instance the attendant doctor accidentally pricked himself with an infected syringe needle and five days later developed relapsing fever with positive blood film.⁶ In 1937 Medulla reported a further three cases infected in Barce.⁷ It is of interest to note that most cases in British troops during the war came from around Tobruk.^{8,9}

The following four cases were seen by us at 82 General Hospital in Benghazi.

Case 1

A Palestinian driver aged 21 had fever, headache, malaise, general aching, vomiting, cough and constipation which started on April 30, 1944. He was admitted to hospital on May 3 when the temperature was 100.6° F (38.1° C). The liver was tender and enlarged one fingerbreadth below the right costal margin. The spleen was tender but doubtfully palpable. The axillary, inguinal, femoral and epitrochlear lymph glands were tender and slightly enlarged; the tenderness in the axillary and inguinal regions being considerable. On May 4 the temperature was morning 102.4° F (39.1° C), evening 104° F (40° C). The lymph glands were less tender and the abdominal tenderness had gone. A blood film revealed fairly numerous spirochaetes. There was much sweating. Next day the morning and evening temperatures were 102° F (38.9° C) and 104.2° F (40.1° C). The white cells numbered 15,000 per cmm (polymorphs 85%, lymphocytes 10%, monocytes 5%, eosinophils 1%). The blood films were again positive. N-acetylsalicylic acid (NAB) 0.6 g was given intravenously. The temperature fell to normal by crisis the next morning and remained down. The lymph gland tenderness had gone and the patient was feeling better. Further doses of 0.6 g of NAB were given intravenously on May 12 and 19. There was no relapse and convalescence was uneventful. The fever lasted six days but he was never more than moderately ill.

This patient had not set foot outside Benghazi for a full month before the onset of his illness.

Case 2

An Italian POW aged 27 started to get vague abdominal discomfort, headache, and feverishness on June 13, 1944. He was admitted to hospital on June 15, when, apart from a temperature of 100.2° F (37.9° C), the only sign of disease was a spleen enlarged two fingerbreadths below the costal margin. There was no history of malaria. Early the next day the temperature had risen to 104.2° F (40.1° C) (Chart 1), and spirochaetes were found in the blood, he was given 0.6 g of NAB intravenously at once. The headache lasted one more day but the fever persisted until June 21 (the ninth day of disease). On June 23 and 30 he received further doses of 0.6 g of NAB intravenously but on June 25 a prolonged irregular pyrexia began which lasted until July 16. Repeated blood slides during this period were negative. At first he complained only of intermittent headache, but by July 4 (the 22nd

CHART 1—Case 2

day) he was vomiting and the headache was severe. Two days later he was also drowsy and uncooperative. The white cell count was 9,600. After a short period of improvement vomiting recurred on July 11, and there was again severe headache, now with moderate neck stiffness, but no Kernig sign. A lumbar puncture produced clear cerebrospinal fluid under a pressure of 180 mm of water, containing 600 cells (all lymphocytes) per cmm, protein 180 mg per 100 ml, chlorides (as NaCl), 700 mg per 100 ml, no spirochaetes. Two days later he was much improved, but still complained of abdominal discomfort. He became symptomless by July 17, but on the 21st the ophthalmologist reported mild bilateral papilloedema. There was further fever (second relapse), after which he remained well. The haemoglobin (Sahli) was 110% on Aug 14. The splenic enlargement diminished but did not disappear.

This patient's movements during the incubation period are not known in detail, but he came from Western Cyrenaica.

Case 3

An Indian pioneer aged 25 first became ill with fever, headache, malaise, and constipation on June 14, 1944. He was admitted to hospital on June 16. The temperature was 100.2° F (37.9° C) later rising to 103.4° F (39.7° C), with a rigor during which spirochaetes were found in the blood. Lungs cough with numerous generalized rhonchi, many expiratory. Abdominal tenderness in the iliac fossae, pronounced on the right but considered not appendicular. The symptoms and fever continued for another day—temperature 102° F (38.9° C). On June 17 NAB 0.6 g, was given intravenously. The fever had gone by the next day, but the chest was not clear of signs until June 21. On June 19 the white cell count was 4,000 (polymorphs, 78%, lymphocytes, 15%, monocytes, 7%). Further intravenous injections of 0.6 g of NAB were given on June 24 and July 1. There were no relapses and convalescence was rapid.

The movements of this patient during the incubation period could not be determined with accuracy, but they were wholly within Cyrenaica, and he had spent much of this time in Benghazi.

Case 4

A British lance corporal aged 33 had sudden onset of headache, malaise, aches in the limbs, feverishness, and sweating on June 19, 1944, and was admitted to hospital the same day. The temperature was 101° F (38.3° C) (Chart 2). There were no other signs of disease, and the blood films were negative. There was a rigor on the next day and he vomited. The first blood film to show spirochaetes was obtained on June 21 and the patient received 0.6 g of NAB intravenously at once. The vomiting lasted one more day and the fever four days in all. The spleen became palpable on the last day of fever. There was no history of malaria. NAB, 0.6 g, was given intravenously on June 28 and July 5. On the 5th began a low irregular fever lasting four days (first relapse), the spleen remained palpable and there was headache and much sweating. A three day symptomless afebrile period followed, after which, beginning on July 13 (the 25th day of disease), there

CHART 2—Case 4

were six days of relatively low-grade fever (second relapse). Headache returned and worsened. On the 15th there was mild neck stiffness. A lumbar puncture on this date produced a clear cerebrospinal fluid under a pressure of 250 mm of water, containing 40 cells (all lymphocytes) per cmm, protein, 45 mg per 100 ml (globulin not increased). A rabbit was inoculated with the cerebrospinal fluid but developed no infection. All symptoms had gone by July 19. The optic fundi remained normal. A low fever developed on the 21st (third relapse) and lasted three days, this pyrexial bout was relatively symptomless. A fourth relapse began on July 28 and lasted four days. Thereafter recovery was uninterrupted. Two more injections of 0.6 g of NAB were given intravenously on July 31 and Aug 7. On the last date the haemoglobin was 80% (Haldane). The spleen became impalpable during convalescence. Numerous blood films from July 6 onwards were all negative.

This patient spent two nights in a billet in Tobruk within the incubation period and may well have contracted the infection there. Otherwise his movements had been inside Benghazi only.

The following is a summary of the symptoms and signs in the four cases.

Abdomen—Vomiting (3 cases), constipation (2), vague pain (1), spleen enlarged (2), spleen tender (1), liver enlarged (1), liver tender (1), tenderness in iliac fossae (1).

General—Fever (4), prolonged irregular fever (1), headache (4), malaise (3), shivering (2), general aches and pains (2), cough (2), noticeable sweating (2), lung rhonchi (1), mild anaemia (1), lymph glands enlarged and tender (1), meningitis (2).

Meningitis—Headache (2), neck stiffness (2), abnormal cerebrospinal fluid (2), vomiting (1), drowsiness (1), papilloedema (1).

Other Points—Relapses: two cases had none, one had two and one had four. Length of pyrexial attacks (all treated), 1–22 days. Length of apyrexial intervals, 2–12 days. Length of stay in hospital: Cases 1 and 3, 20 days; Case 2, 73 days; Case 4, 69 days.

Spirochaetes were scanty in the blood films of Cases 2, 3 and 4, in Case 1 they were moderately plentiful. The effect of neoarsphenamine treatment was poor.

Discussion

It was not possible to carry out investigations to discover the species of spirochaete. However, none of the patients was lousy, and there was no reason to suppose that any had been in contact with lice. It can be assumed with a fair degree of certainty that the spirochaetes were tick-borne in origin, although it is just possible that in Case 1 they were louse-borne. The variation in the symptomatology and clinical courses of these four cases illustrates well the different forms that tick-borne relapsing fever can present. The rather long initial fever of Case 1 is more like the louse-borne type. The high incidence (2 out of 4) and type of neurological complications and the poor response to treatment with intravenous arsenicals are consistent with the findings of others reporting relapsing fever from Cyrenaica and the Egyptian western desert, notably Medulla,³ Cooper,¹⁰ Bulmer,¹¹ Scott,¹² McAlpine,¹³ and reports and publications by Army medical consultants, MEF.^{8, 14, 15}

The question of the vector in Cyrenaican relapsing fever is of some interest. The origin of the infection in Case 1 at least was Benghazi, Case 4 very possibly contracted it in Tobruk, a well-known infective centre.^{8, 10, 13, 14} In Cyrenaica, as in America, Palestine, Southern Russia, and more recently, Cyprus,^{16, 17} the tick-borne disease, once recognized, will probably be found to be of wide potential if not actual distribution, corresponding to a wide scattering of *Ornithodoros* ticks capable of transmitting *Spirochaeta duttoni*. It is quite possible that louse-borne relapsing fever also occurs, serving to complicate the picture, the local inhabitants are frequently lousy. We have been informed by Major Walmsley that groups of nomadic Libyans in the hills of Cyrenaica periodically have minor epidemics of relapsing fever in their small communities. It is possible that this might be a result of camping in some spot infested with infective ticks, but such epidemics may be louse-borne or even mixed. Medulla³ spoke of "the endemic illness in the highland districts" which is "transmitted by lice and by different *Ornithodoros* found in Cyrenaica." Manson-Bahr¹⁸ states that the louse-borne infection is prevalent among the Bedouin Arabs of North Africa, especially in the winter months.

In most of the Italian papers reporting cases no indication or conjecture is given as to the source of the spirochaetes. But note was periodically made that patients had had no contact with lice.¹⁹ On clinical and epidemiological considerations Medulla⁴ thought that the four cases he reported in soldiers from the Cyrene Jebel were probably tick-borne, he suspected two *Ornithodoros* ticks known to be present in the district. In 1927 Lodato collected specimens of an argasid tick at Gadhames, Tripolitania.²⁰ Franchini and Taddia,²¹ recording cases at Bardia of what was probably "tick-bite fever," reported the finding of "a new species of *Ornithodoros* that lives in grottoes, probably on small rodents." The ticks from both these collections were apparently first thought to be *Ornithodoros lahorensis* Neumann, but were identified by Maria Tonelli Rondelli as *O. franchini*, n. sp.^{21, 22}

Parrot²³ described in detail a new *Ornithodoros* tick found in the Algerian Sahara, he named this tick *O. foley*, n. sp. Roubaud and Colas-Belcour²⁴ described a new tick from French North Africa which they named *O. delanoei*, n. sp. This tick was differentiated from *O. foley* Parrot and *O. lahorensis*. From a comparative study these authors came to the conclusion that *O. foley* Parrot and *O. franchini* Rondelli were probably the

same. However, Franchini^{25, 26} thought they were different species and claimed that he first described the tick later called *O. franchini* Rondelli in 1927. Warburton²⁰ considers that *O. franchini* is probably the same as *Argas brumpti*, Neumann, 1907, a tick which has characters of both *Argas* and *Ornithodoros* genera.

Garibaldi² summarized the geographical distribution of argasid ticks in Italian North Africa. He stated that *Argas persicus* (Olen) had been found at Benghazi, Kufra, Marada, Tobruk, and Tocrá, *O. savignyi* Audouin at Augila, Kufra, Ghalo, Giarrub, and Marada, *O. franchini* at Porto Bardia, Kufra, and Marsa Lucch (the latter being between Bardia and Tobruk, on the coast). He stated that *O. moubata* Murray and *O. lahorensis* had been found only in Tripolitania, although Franchini¹⁹ said that these two ticks had also been found in Cyrenaica. Previously Zavattari,²⁴ Gaspare,²² and Franchini¹⁰ had engaged in a controversy as to the presence of *O. moubata* in Libya—that is, in Italian North Africa. Franchini³¹ stated that *O. savignyi* had not so far been found naturally infected with spirochaetes in Cyrenaica, but he was able to transmit *S. duttoni* to white mice through nymphs of *O. savignyi* from Agedabia. However, Kirk²² states that in this tick the infection is not hereditary and that *O. savignyi* has never been found infected in nature.

In a publication by GHQ, MEF¹⁵ it is stated that relapsing fever is "not uncommon" in "all parts of the western desert." Dewar and Walmsley³³ mentioned only ticks as vectors in the Egyptian western desert and in Libya (presumably they mean Cyrenaica). Stuart²⁴ reported that the louse-borne type is said to be very prevalent in Libya—that is, Italian North Africa—and that the tick-borne form also occurs there. He also said that three recognized carriers of the disease have been recorded from Libya—namely *O. moubata*, *O. savignyi*, and *O. lahorensis*. We have been unable to find any evidence in the literature that the last-named should be incriminated as a vector in Cyrenaica. Indeed, in spite of a considerable volume of work performed with *O. lahorensis* in other parts of the world, although there are some confusing opinions, no one has ever produced reliable evidence that it can transmit any strain of relapsing-fever spirochaete^{24, 34, 35}. The same remarks apply, but with more force to *Argas persicus*, a tick which in the past has been often wrongly spoken of as a transmitter of human spirochaetosis^{32, 40, 43, 51, 52}.

It must be admitted that a study of the literature relating to relapsing fever in Italian North Africa leaves one with a rather confused picture as to the vectors responsible. No one so far as we are aware has ever inoculated human blood infected with Cyrenaican strains of relapsing-fever spirochaetes into laboratory animals in order to determine the vector (louse or tick). Little work on that aspect of the disease in this area has been possible during the war. Neither time nor facilities were available to us for laboratory or field work, and we know of only two collections of ticks made from this region during the war. One of these was at Tobruk in 1942 by Major Joc Bryant, R.A.M.C., and after leaving his hands this collection has not been traced. Bryant stated that his ticks were certainly *Ornithodoros* sp. The other collection consisted of one tick produced by a private soldier on admission to hospital at Tobruk with relapsing fever. The patient stated that he had bitten him, but there is no record of the time of onset of bite to onset of fever.³⁶ This tick was sent at once to Prof. Adler who informs us that during the war he also received two ticks from the Egyptian western desert as three ticks being the same species. We are informed by Prof. Adler and Dr. Theodor that all

the ticks they received from the western desert were *O. tholozani* (syn. *papillipes*), Laboulbène and Mégnin. This is a new piece of evidence of considerable value. Hitherto *O. tholozani* had not been found west of Cyprus.¹⁶ Transmission experiments performed with these ticks showed the two ticks from the western desert to be free of infection, but the tick from Tobruk was proved to be naturally infected with relapsing-fever spirochaetes (Adler and Theodor—personal communication)³⁸.

A final point of much less importance may be raised. It must be remembered, especially in connexion with cases occurring in towns, that some evidence has been produced that bed-bugs (*Cimex lectularius*)^{19, 67, 72, 73} and dog-ticks (*Rhipicephalus sanguineus*)^{80, 87} may cause isolated cases of relapsing fever. However, the evidence for this is by no means conclusive. The former are widespread in North Africa, and the latter have been identified in numerous places in Cyrenaica.²⁷

Summary

Four cases of relapsing fever, probably tick-borne, are described. All contracted the infection in Cyrenaica, one was infected in Benghazi.

Two of these cases were complicated by meningitis, one of which had papilloedema. In these and other respects the four cases were of similar clinical type to cases from this area described by other authors.

The relevant literature, especially the Italian, is discussed.

Before the war Italian workers claimed to have identified one possible and two known carriers of relapsing-fever spirochaetes in Cyrenaica respectively—*O. foleyi* Parrot (syn. *O. franchini* Rondelli), *O. moubata* Murray, and *O. savignyi* Audouin.

Recently Adler and Theodor have identified ticks collected from Tobruk and the Egyptian western desert during the war as *O. tholozani*, Laboulbène and Mégnin, and have shown the Tobruk tick to be naturally infected with relapsing-fever spirochaetes.

Our thanks are particularly due to Prof. S. Adler and Dr. O. Theodor, of Jerusalem, for their kindness in supplying information about the ticks from the western desert. Thanks are also due to Prof. P. A. Buxton, Prof. R. M. Gordon, Brig. S. Smith, late R.A.M.C., Col. J. S. K. Boyd, late R.A.M.C., Dr. R. Kirk, Sudan Medical Service, and Major J. M. Drennan, R.A.M.C., pathologist, for valuable help in compiling this paper.

TWO CASES OF FERROUS SULPHATE POISONING

BY

JAMES THOMSON, MB, FRCP

Paediatrician Royal Infirmary Dundee Lecturer in Child Medical Diseases of Children University of St Andrews

After reading Dr Gilbert Forbes's (1947) paper on poisoning with a preparation of iron, copper, and manganese I am prompted to record two further cases. It would seem that the condition may not be rare, and it is certainly one demanding increased precautions to prevent it.

Case 1

A 16 months old girl was admitted to the Dundee Royal Infirmary on May 3, 1944. About 10.30 a.m. on that date she obtained a packet of 40 tablets, each containing ferrous sulphate exsic gr 3 (0.2 g) copper sulphate gr 1/25 (2.6 mg) and manganese sulphate gr 1/25. She swallowed all but one of these, and vomited almost at once bringing up one tablet. Her mother gave her salt and water to drink, when about 12 more tablets were vomited. She thus retained about 26 of them. The child then became hot and drowsy and kept coughing and vomiting. The vomit contained mouthfuls of dark blood stained materials.

She was admitted to hospital at 11.50 a.m. On examination she was rather pale, and was coughing and vomiting. The vomit was blood stained. There was no rash or marked drowsiness. The temperature was 96° F (35.6° C), pulse 140, and respirations 24. The pulse was of slightly diminished volume. Her tongue was somewhat furred, the fauces were healthy. The abdomen was slightly distended. There was neither tenderness nor resistance on palpation. Nothing abnormal was noted in the central nervous system. Gastric lavage with a sodium bicarbonate solution was carried out, and brownish material was obtained. Some normal saline was left in the stomach. "Nepenthe" 1/2 min (0.03 ml) was given at once and 2½ gr (0.16 g) of bismuth carbonate was given four-hourly.

In the evening she was breathing heavily, but was otherwise comfortable. There was no cyanosis during the night. No vomiting occurred, but one loose stool containing mucus and dark blood was passed. The temperature rose suddenly to 101.2° F (38.4° C) at 7.30 a.m. on the second day, her breathing became very difficult and she became cyanosed, she struggled seemed to choke on inspiration, and died immediately.

Post-mortem Report (Dr G H Smith).—A well nourished female infant rather cyanosed. Thorax Heart and pericardium normal, both lungs show areas of patchy collapse and rather oedematous mucopurulent material in bronchi and trachea no oedema of glottis. Abdomen No free fluid in peritoneal cavity and no evidence of perforation. Stomach Somewhat dilated. There is a large amount of brownish black fluid present. The gastric mucosa is the seat of intense inflammatory change and there is a marked degree of necrosis and sloughing limited to the crests of the longitudinal rugae. Necrotic material from the stomach gives an intense iron reaction the appearances being consistent with those due to corrosive poisoning. Numerous haemorrhagic points are apparent. Microscopical section shows necrosis of mucous membrane extending down to muscle. Intestines Apart from a few patches of congestion in the upper jejunum, the intestines are healthy and the only contents present are black semi fluid material resembling altered blood. Those contents are confined to the lower bowel, chiefly the pelvic colon. Liver There is passive congestion. Neither hepatitis nor necrosis is present. Gall bladder and pancreas Healthy. Spleen Healthy but congested. Kidneys and suprarenals Healthy apart from venous engorgement. Ureter and bladder Normal. Head Brain and meninges healthy.

Case 2

A boy aged 2 years swallowed about 10 tablets similar to those mentioned above about 9.30 a.m. on March 4, 1947. Approximately half an hour later he began to vomit green bile.

Two tablets were returned whole. There was no change in his colour. His colour became waxy but had improved before admission to hospital the same day at 2.5 p.m. He was very thirsty. A stool passed later in the day was dark and gave the guaiac reaction for blood.

On admission he was rather flushed listless and drowsy. His pulse was regular and of good volume. There was neither tenderness nor abnormal resistance over his abdomen. Treatment consisted of mist magnesium hydroxide and bismuth along with glucose and saline. Later changed to milk and subsequently to milk diet. By March 6 the vomiting had ceased and on the 9th the stool was normal with no blood. On the 13th the child was very well but the stool was dark and the guaiac test positive. He had had no meat since admission. On the 16th the stool was again dark and on the 18th he was well and there was no melena.

Comment

Ferrous sulphate poisoning is a serious risk in view of the wide spread use of this type of tablet. It is important that they should be kept in a place where children cannot obtain them, and that their potential toxicity should be realized by the profession.

The first patient died after consuming about 26 tablets. The second survived after retaining about eight. B.A.L., which was referred to in an annotation (*Journal*, March 22, 1947 p. 386) was not available for the former case in 1944 and was not required in the latter one.

An old name for ferrous sulphate is green vitriol.

It is important to realize that these cases and the two quoted by Forbes have all resulted from gross overdosage.

Medical Memoranda

Chronic Lymphatic Leukaemia in Man of 84

The following case in which the leucocytes outnumbered the erythrocytes seems worth recording on account of the advanced age of the patient.

CASE REPORT

A retired 84 was admitted to Chase Farm Hospital at mid-day on July 14, 1946, with the preliminary diagnosis of pernicious anaemia. He was not fit for interrogation but his daughter stated that he had been yellowish in appearance and breathless on exertion for some time. On examination he was well covered, with a pale but not lemon yellow tint. His tongue was smooth. Rales were heard throughout both lungs, and there was a soft systolic murmur at the apex. The liver was palpable three fingerbreadths and he had two finger breadths below the costal margin. Reflexes were normal, and ankle jerks present and equal, plantar responses negative. Lymph nodes were not palpable in the neck or axilla. At 4 p.m. he was given 2 ml of neohepatex intravenously and 1 ml of analgamin intramuscularly. He died at 4 p.m.

Autopsy showed erythrocytes 680,000 per c.mm., leucocytes 250,000 per c.mm., reticulocytes 19.6%, thrombocytes, 100,000 per c.mm. Because of the high bilirubinaemia it was found that there was a moderate anaemia by Haldane's method. It was found that the blood was old, and that the venous blood was old. The blood did not show normal clotting. The differential blood count (2,000) showed a predominance of small lymphocytes. Macrocytosis was evident. There were numerous reticulocytes and many of the red cells were old. The venous blood showed a moderate anaemia. The plasma protein was 7.7%. The plasma urea was 250 mg. per 100 ml. The plasma creatinine was 0.8 mg. per 100 ml. The plasma uric acid was 4.5 mg. per 100 ml. The plasma cholesterol was 250 mg. per 100 ml. The plasma triglycerides were 150 mg. per 100 ml. The plasma glucose was 100 mg. per 100 ml. The plasma albumin was 4.5 g. per 100 ml. The plasma globulin was 3.2 g. per 100 ml. The plasma total protein was 7.7 g. per 100 ml. The plasma urea was 250 mg. per 100 ml. The plasma creatinine was 0.8 mg. per 100 ml. The plasma uric acid was 4.5 mg. per 100 ml. The plasma cholesterol was 250 mg. per 100 ml. The plasma triglycerides were 150 mg. per 100 ml. The plasma glucose was 100 mg. per 100 ml. The plasma albumin was 4.5 g. per 100 ml. The plasma globulin was 3.2 g. per 100 ml. The plasma total protein was 7.7 g. per 100 ml.

14 lb (680 g) and was of firm consistency, the cut surface showed enlarged Malpighian bodies. The lymph nodes were moderately enlarged in the mediastinum, abdomen, and groins.

COMMENTARY

The case was remarkable for the following reasons: the age of the patient, the leucocytes exceeded the erythrocytes, a reticulocyte count of 19.6% the unusual degree of bilirubinaemia, the high plasma uric acid, and the possibility of coexisting pernicious anaemia. Panton and Valentine (1929) found that the average age incidence in 25 cases of chronic lymphatic leukaemia was 55 years, but the age of the oldest patient was not recorded. Biggs (1936) reported a case of lymphatic leukaemia in a man aged 83. Emile-Weil *et al* (1938) described a series of cases of lymphatic leukaemia in patients aged from 64 to 81 years, the man aged 81 being the oldest leukaemic patient that they had seen. Although the leucocytes rarely outnumber the erythrocytes, high counts have occurred in other aged leukaemic patients. In Biggs's case they numbered 245,000 per c.mm. and I found 418,000 per c.mm. in a woman aged 75. Emile-Weil's cases however, were all crypto leukaemias or subleukaemic forms the highest count being 15,000 per c.mm.

The blood for the reticulocyte enumeration was taken 20 minutes after the injections of liver extract. It is, however, difficult to believe that the high reticulocyte count resulted from the injections, moreover, Roth (1943) has reported a leukaemia with 18% of reticulocytes. It is of interest to note that the patient's colour never suggested the high degree of bilirubinaemia present. The raised plasma uric acid was possibly associated with the numerous nucleated red cells or the increased fragility of the lymphocytes as shown by the smear cells. The signs of subacute combined degeneration of the cord suggested possible coexisting pernicious anaemia, but the data are not complete enough for a satisfactory diagnosis. Wintrobe (1942) considers that there have been only four acceptable cases in which the two diseases have existed simultaneously.

I wish to thank Dr P. Hamill under whom the patient was admitted for permission to publish the case.

T. H. TIDSWELL M.R.C.S. L.R.C.P.

Trichobezoar

The following case is placed on record owing to the large size of the hairball and because of the few symptoms it caused.

CASE HISTORY

A girl aged 18 was admitted to the Clayton Hospital, Wakefield on April 5, 1946. She had been in good health until 10 days previously, when she started complaining of left sided abdominal pain "knife like" in character and associated with anorexia.

On examination a large tumour could be felt extending across the upper abdomen, the shape of a dilated stomach. An x-ray examination of the stomach and duodenum was carried out and Dr Rose reported as follows: "This seems to be a very rare and interesting case of a huge hairball (trichobezoar) forming almost a cast of the lumen of the stomach."

At operation on April 12, Mr E. R. Flint removed the hairball. The patient developed an acute dilatation of the stomach on April 14, this responded to treatment, and she was discharged from hospital on May 8. The hairball measured 17 in (43 cm) along the greater curvature, 15 in (38 cm) along the lesser curvature, and 8 in (21 cm) in the largest diameter. The girl admitted to eating her hair as a child mainly just before she went to sleep, but stated that she had not done so since she was 12 years of age.

ARTERIAL THROMBOSIS

Thromboses Artérielles Physiologie Pathologique et Traitement Chirurgical By René Leriche in collaboration with Dr. Ivan Bertrand (Pp 537 illustrated 600 francs) Paris Masson et Cie 1946

Two of Leriche's earlier works—*The Surgery of the Arteries* which appeared in 1943, and *The Surgical Treatment of Vasmotor Disorders of the Arteries* published in 1945—constitute with the present volume a rich store of facts observations and clinical experience, but also stand as a permanent memorial to the vision and industry of the author as a pioneer in a field of surgical endeavour with which his name will always be associated. Though he has already contributed so much we look forward with eager anticipation to the next publication, and with good reason, for he devotes the early pages of his book to an eloquent plea for a revival in France of an interest in experimental surgical research.

After reviewing the causes of arterial thrombosis, among which he stresses the influence of endocrine disorders upon blood vessels, Leriche lays down certain rules about the relationships which exist between the state of the arterial coats and the extent of thrombosis and the organization of clots, and also about the ischaemic effects of thrombosis, which are due partly to mechanical obstruction of the arterial lumen, but also to neurogenic spasm of the more distal vessels. By the onset of spasm, which may be precipitated by remote factors such as haemorrhage, inflammation, cold, or a heart lesion thrombosis suddenly becomes manifest. But the most important consideration in prognosis is the effect upon collateral vessels: thrombosis is well tolerated if it is localized and in the proximal part of a limb, but it is serious if the clot blocks many collaterals and disastrous if the process spreads to involve the companion vein.

The detailed description of the clinical manifestations of arterial thrombosis is arranged in three parts, the first dealing with traumatic thrombosis following contusion or rupture of arteries. In treating a wounded limb which shows signs of ischaemia the mere exploration of the artery and blocking the sympathetic nerve supply is not enough. If the artery is in spasm it should be stripped of its outer coat, if it is thrombosed or badly contused the affected part should be excised, and the sympathetic block must be repeated as often as is necessary. Arterectomy is undertaken in order to abolish vasomotor spasm as well as to prevent extension of the clot. These measures can abolish the pain of the causalgia type which appears immediately after wounding and will prevent Volkmann's contracture. The "chronic contusion" of arteries by pressure of a cervical rib, a crutch or a bone after a dislocation or fracture is also described.

In the second part the author discusses spontaneous thrombosis in obliterative arteritis, devoting special attention to thromboangitis obliterans. One of the few criticisms which may perhaps be allowed is that more attention has not been paid to the not uncommon thrombosis, of the popliteal artery especially in the absence of Buerger's disease, and little notice is taken of the relation of the arterial blood pressure and arteriosclerosis to spontaneous thrombosis. The most interesting feature in this section is the author's support for the theory of the endocrine origin of thromboangitis obliterans, and his advocacy of unilateral adrenalectomy (incidentally without a warning about the danger of removing a solitary suprarenal) in addition to lumbar ganglionectomy in its treatment.

In the third part he considers arterial thrombosis apart from the limbs—particularly at the bifurcation of the aorta and in the coronary arteries. The frequency of aortic thrombosis as quoted here seems astonishing at first sight but it must be that the symptoms of fatigability atrophy and trophic disorders in the legs, associated with impotence are often attributed to some nervous or constitutional disorder the diagnosis being missed because the absence of arterial pulsation distal to the bifurcation of the aorta has not been noticed. He advocates high lumbar ganglionectomy and, in favourable cases, excision of the bifurcation for this condition. In the section on coronary

thrombosis Leriche gives a complete review of angina pectoris in which he has had a special interest for many years. In this as in many other chapters, those who are already familiar with his writings will recognize some of the lessons they have learnt from him before, but the fact that they are as welcome and as satisfying when repeated as when they were first heard is a high tribute to the author's genius.

X RAYS AND THE SKIN

X-Rays and Radium in the Treatment of Diseases of the Skin By George M. MacKee, M.D., and Anthony C. Cipollaro, M.D. Contributor, Hamilton Montgomery, M.D. Fourth edition, thoroughly revised (Pp 668, 321 engravings and 4 coloured plates 50s) London Henry Kimpton 1946

This edition of what is probably the best book in the English language on its subject has been thoroughly revised. It is no longer that with the passage of time a therapeutic weapon so potent as x rays becomes narrowed in its application rather than widened, yet this as the authors point out, is what has happened. In the early days x rays were employed in many conditions in which later experience has shown them to be either unsuitable or less suitable than other agents. Nevertheless it is still true, as Dr W. A. Pusey remarked over thirty-five years ago, that roentgen therapy is the most widely useful addition to the treatment of skin diseases that has been made. The importance of the ill-effects of x rays may be judged by the space given to the consideration of radio-dermatitis and radiocarcinoma. The pitfalls which lie in the path of the foolhardy are illustrated by the chapter on the medico-legal aspects of the subject.

The authors' account of cutaneous radiotherapy is well proportioned. The effects of radiation on living tissues are fully considered, and also the methods used and the results obtained in the treatment of all the varieties of skin disease which may be submitted to radiotherapy. Dermatologists will find this part of the book the most interesting. The authors hold the balance evenly between the extremes of uncritical optimism and unrelieved pessimism, and they found their conclusions on a comprehensive knowledge of the literature of the subject.

The format of the volume is well up to the best American standards, the clinical photographs are excellent and so are the four coloured plates, all of which are devoted to various aspects of x-ray disaster—an allocation somewhat out of proportion. However, any temporary false impression which examination of the coloured plates alone might convey will be amply dispelled by further study of the book, and we commend it unreservedly to all who are interested in cutaneous therapeutics.

LIVES OF THE OLD

Old People Report of a Survey Committee on the Problems of Ageing and the Care of Old People under the chairmanship of B. Seebohm Rowntree, C.H., LL.D. (Pp 202 illustrated 3s 6d) London Published for the Nuffield Foundation by Geoffrey Cumberlege, Oxford University Press 1947

For the first time an attempt has been made to discover how old people live and to assess their particular needs. The Nuffield surveyors' report discloses a disquieting state of affairs. Most old people continue to reside in their own homes, but the conditions under which they live vary greatly. Many are well cared for, some live in a single room where they eke out a precarious and miserable existence. Many—and this also applies to those who live with their relatives—would be willing to enter a hostel or home for old people if such were available. The number of suitable homes is small, and any one that opens is at once overwhelmed with applicants seeking admission. Some are nothing better than "farms" for the aged. The surveyors recommend that all such voluntary homes should be open to inspection, but it is difficult to define such places in terms that would exclude a hotel or boarding house.

The report emphasizes that, though dire poverty is no longer a real problem for the aged, loneliness may be. Opening clubs for them may relieve it, but this provision is often difficult at present. An adequate supply of food is another difficulty. Many old people find shopping, with its waiting and queueing

almost unbearable, and live on a miserable fraction of their rations. There is evidence that an appreciable amount of preventable ill health, leading often to admission to hospital, is caused by underfeeding. The provision of meals by mobile canteens supplied if necessary from Civic Restaurants, would make a great difference to the comfort of many old people.

The surveyors discuss at some length the employment of the elderly in suitable work and quote an impressive amount of evidence showing that they have a valuable contribution to make towards the nation's wealth—an important observation on our ageing population and one that should be studied. In a short note a medical subcommittee outlines a programme of long term research into the factors that lead to ageing and other problems. The subcommittee remarks upon how little work has been done on the relationship between economic and social environment and the disabilities of old age. Inquiries are being carried out in Wolverhampton and Glasgow which should be fruitful. The lack of suitable homes in this country for old people of all social classes is notorious. The Poor Law has made its not very satisfactory contribution and the rest has been left almost entirely to voluntary bodies.

AMULREE

FOOD IN THE HOME

Nutrition in Public Health. By Lucy H. Gillett, M.A. (Pp. 303, illustrated 14s.) Philadelphia and London: W. B. Saunders Company, 1946.

Lucy Gillett has written this book for the public health nurse of America. It should interest health visitors and midwives in England provided they keep in mind the great differences in the food situation between the two countries. Meat purchases, writes Lucy Gillett, 'need careful watching to prevent them from crowding vegetables and milk from family meals. Fats should not be used too freely.' The English reader will also study the food needs per week in tables 18, 19, and 20 with some of the envy depicted on the faces of the two children in the advertisement for a well known brand of gravy powder. The book is based on sound common sense, is easy to read, and does not over simplify a complex subject. The scientific principles of nutrition are made clear to the housewife, she is taught how to plan a meal for all circumstances and how to budget economically.

Men and women consume the following approximate minimum amounts of foodstuffs per week: milk 41-6 quarts (4.8-6.8 litres), eggs, 4, meat 2 lb (0.9 kg), fats 12-16 oz (0.34-0.45 kg), sweets, 12 oz (0.34 kg). The author recommends that for a low income family of four persons with the man working at a desk all day, the woman doing all the housework, a boy of 14 who plays football, and an athletic girl of 10, the weekly marketing list in the late fall should include 9 quarts (10.2 litres) of fresh milk, 12 tall cans of evaporated milk (equal to 10 quarts (11.3 litres) of milk), 6 oz (170 g) of cheese, 1 dozen eggs, 8 lb (3.6 kg) of meat, 3½ lb (1.5 kg) of fats, 3 lb (1.4 kg) of sweets, 19 lb (8.6 kg) of cereals, and 24 lb (10.6 kg) of vegetables and fruit.

One might wonder why a book on the principles of nutrition should be required in the land of plenty, but the fact is that educating the housewife is more necessary where food abounds than where supplies are hoarded and doled out in exchange for coupons. Scarcity has taught us much, there is now greater need for such education where rationing is unknown.

FRASER BROCKINGTON

The sixteenth edition of *Stedman's Practical Medical Dictionary* (London: Baillière, Tindall and Cox, 42s.), edited by Dr N. B. Taylor, contains a new etymological section on medical terms. Mr A. E. Taylor has tabulated the Greek and Latin roots from which so many of these words are built up, and the student learning, for example, the meaning of the root 'sehi' (from the Greek *σῆω*) will recognize it in such words as schizophrenia and schizogenesis. Appendices include tables of weights and measures, the chemical elements (though neptunium and plutonium are not shown), and a list of pathogenic micro organisms with the old and new nomenclature. Though the spelling preferred is American words are listed also under their English form—for instance, anemur and anemur. Brief historical notes on men whose names are used eponymously enliven the text. Students and practitioners will find that 'Stedman's' is a valuable reference book.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Synopsis of Operative Surgery. By H. L. Mobley, M.D. F.A.C.S. 2nd ed. (Pp. 416, 30s.) London: Henry Kimpton, 1947.

A summary of the technique of operative surgery, this edition includes an account of recent advances, many illustrations.

Janus, the Story of a Doctor. By John Plesch. (Pp. 579, 18s.) London: Victor Gollancz, 1947.

An autobiography by Prof. Plesch, with a portrait of Einstein by the author and anecdotes about many of his famous friends including the Curies, Wassermann, Einstein, Fritz Kreisler, and Tescanini.

Dynamic Aspects of Biochemistry. By Ernest Baldwin, B.A. Ph.D. (Pp. 457, 21s.) Cambridge: University Press, 1947.

Designed as an introductory textbook to biochemistry for students specializing in this subject.

Forensic Medicine. By Keith Simpson, M.D. (Pp. 335, 16s.) London: Edward Arnold, 1947.

A textbook of forensic medicine and toxicology intended for medical students, many illustrations.

Scoliosis. By Beatrice Woodcock. (Pp. 111, 11s. 6d.) Oxford: University Press, 1947.

Described as a practical and simple approach to the treatment of scoliosis with many illustrations.

Tutoring as Therapy. By Grace Arthur, Ph.D. (Pp. 125, 8s. 6d.) New York: The Commonwealth Fund, 1946.

By 'tutoring' the author means the individual teaching of children who have the intellectual capacity to understand school work but suffer from some mental or physical disability. She discusses the selection, training, and administration of teachers as well as therapy.

A Touch of Glory. By Frank G. Slaughter. (Pp. 272, 10s. 6d.) London: Jirrols, 1947.

A novel about a doctor's struggle against medical 'rackets' in Mexico.

La Reticulose Histio-monocytaire. By P. Carré. (Pp. 195, 350 francs.) Paris: Masson, 1946.

A monograph on a group of pseudo leukemias—malignant diseases of the reticular stroma and the hemopoietic system. In French.

Handbook of Correctional Psychology. Ed. by Robert M. Lindner, Ph.D., and Robert V. Scherer, M.D. (Pp. 691, \$10.00.) New York: Philosophical Library, 1947.

A symposium by various authors on the practical handling and rehabilitation of prison inmates.

Principles and Practice of Obstetrics. By Joseph B. De Lee, M.D., and J. P. Greenhill, M.D. 9th ed. (Pp. 1011, 50s.) Philadelphia and London: W. B. Saunders.

This edition includes new material on foetal erythroblastosis, premature labour, postpartum, and the care of premature babies.

Experiences with Folic Acid. By Tom D. Spies, M.D. (Pp. 110, 21s.) Chicago: The Year Book Publishers, 1947.

A monograph on the use of folic acid in the treatment of megaloblastic anaemias.

Improvised Equipment in the Home Care of the Sick. By Evelyn M. Olson, R.N. 4th ed. (Pp. 265, 7s. 6d.) Philadelphia and London: W. B. Saunders, 1947.

An illustrated manual on improvised first aid and nursing measures intended primarily for those who nurse the sick at home.

The Population and Epidemics of Exeter. By Ransom Pickard, C.B., C.M.G., M.S., F.R.C.S. (Pp. 83, No price.) Exeter: James Townsend, 1947.

An account of the population changes and epidemics of communicable diseases in Exeter since the 14th century.

Maladies et Syndromes Rares ou Peu Connus. By Prof. A. Aimes. (Pp. 205, 300 francs.) Paris: Masson, 1946.

Short notes on a large number of rare diseases with bibliography.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 10 1947

DAY NURSERIES AND INDUSTRY

During the war local authorities were urged by the Ministry of Labour to provide day nurseries for infants and children under 5 years of age whose mothers undertook full-time industrial work. These nurseries were established not for the sake of the mothers or children but with the specific object of increasing the woman-power available to the State, and mothers with more than one child, or at most two children, or mothers unable to work during their own illness, were therefore not allowed to use these nurseries. Of the women in industry at the beginning of 1945 about 1% had children in day nurseries.¹ After the war, though many nurseries were closed, the majority remained open. The shortage of man-power is still acute and is likely to remain a feature of our social life for years to come. So the Ministry of Labour is once more pressing for more full-time day nurseries. In some areas, particularly in the cotton spinning districts of the North-West, firms are themselves providing nurseries or crèches for the infants and children of their women employees. Under existing legislation such industrial nurseries are not subject to the control of any outside body and may be good, bad, or indifferent. For many decades past, members of our profession, as well as social reformers, have urged that the employment in industry of mothers of young children is detrimental to the well-being both of the children and of the family, and that women should be encouraged and helped to look after their own young children at home. Have we reason now to reverse this policy? Our answer should depend on whether the provision of nurseries does in fact liberate essential woman-power, whether the physical and mental health of mothers and children is affected advantageously or adversely, and whether home life does or does not suffer thereby. Information is available on some of these points.

The women released by admission of their children to day nurseries cannot give steady service, since when the child is sick the mother must stay at home, and therefore they, like their children, presumably have an absentee rate of 25% and often more. Because of the absentee rate of children day nurseries admit to their registers some 20% more than they can accommodate. The investigations of F Grundy,² Medical Officer of Health for Luton, are illuminating. After reviewing the figures available to him (number of mothers with two children in nurseries, number of children attending half-days or absent, number of nursery workers) he estimated that the provision of wartime day-nursery accommodation for 100 children would release 27 persons for whole-time work in industry. He also esti-

mated the net annual cost of the nursery service (excluding administration costs and capital expenditure, but including loan charges on capital) as £192 per person released for whole-time industrial work. That was in 1943, and costs have risen steeply since then. Grundy's figures ignore all labour absorbed by the nurseries except that of women directly employed in them. To this, therefore, should be added the man-power consumed in medical supervision, in administration, clerical work and accountancy in the local authority offices, in laundry work, and in provision of equipment and replacements—a heavy item. When an absent child is sent to hospital the mother may remain in work, but trained labour is absorbed by the hospital services provided. It is obviously impossible to compute all this labour force accurately. We are paying a large subsidy for every mother thus entering industry, but it seems doubtful whether the nurseries do not absorb more labour than they free.

Every doctor, but not every business man requiring labour, knows that to congregate children in large groups increases the incidence of infection among them, and the younger the child the greater the risk. In an article in the last and present issues of the *Journal* M McLaughlin gives data on the incidence of certain infections in day nurseries, based on work carried out over a period of 12 months in Birmingham, where work for the welfare of children is well known to be of a high standard. The results are clear-cut and striking: respiratory tract infections were two to eight times more frequent in children attending local authority nurseries than in a control group living in their own homes. The degree of difference in infection rates may surprise many doctors. It is true there were inevitably various differences in the social background of children in the two groups, but that this did not invalidate the comparison is shown by a previous large scale investigation³ organized (like the Birmingham investigation) under the auspices of the Medical Women's Federation, and carried out by child welfare medical officers in twenty-two local government areas in Great Britain, the results being analysed by W J Martin. This showed that nursery children examined within one week of admission, and home children examined as controls, had an approximately similar incidence of enlarged tonsillar glands, of mouth breathing, and of bronchitis, but that the incidence of these conditions rose strikingly in children over 6 months in the nurseries. Hence we can legitimately conclude that nursery life caused a deplorable increase in respiratory tract infection. McLaughlin found that 22.6% of the boys and 16.0% of the girls at nurseries suffered from chronic nasopharyngeal infection, as against 2.8% and 2.0% among home children. What this portends in chronic sinusitis, and its sequelae, in later years among these nursery children is still unknown. Measles was epidemic in Birmingham during the year of the investigation, and the percentage of children under 18 months of age developing measles was more than six times greater in the nursery group than in the home group. Thus nursery life greatly increased the proportion of children developing measles when ver-

¹ Menzies H. *Lancet* 1946 2 499² Statistical Report to the Luton Borough Council 1943³ *British Medical Journal* 1946 2 117

young the fatality rate among cases of measles in London fever hospitals before the war was about nine times as great for children under 2 as for those aged 5 to 9 years. Such is the cost of life in a day nursery to children's health—and this cost cannot be offset by the interesting fact that children over 3 years of age in the nurseries usually averaged about half to one pound heavier than the controls living at home—a fact which may result from the increased rations available to day nursery children under our present rationing schemes.

There exist no statistical data on the comparative mental health of children living at home and of children in day nurseries, and controversialists will no doubt continue to adhere to their own diverse opinions as to the relative value of home life and nursery life until statistical data are available. There is, however, a large body of opinion in support of the view that at least under the age of 3 years the child needs the security of his home and of proximity to his mother, and often suffers severely from being left in a nursery.

Double responsibilities and double work, in the home and in the factory, are well-recognized causes of illness among women workers. The task of shopping, washing, cleaning, mending, and cooking, and of tending husband and small child, in addition to doing a man's full-time work in factory or shop, is superhuman, and something must go to the wall. M. Back⁴ has noted the squalor in the homes of some of these mothers. Some women who are not forced to earn for themselves and their children undoubtedly prefer factory life to minding the baby in the cramped quarters of their homes, though probably most of even this minority would choose to stay at home were they aware of the danger to children's health involved in nursery life. Menzies¹ has drawn attention to the large number of children withdrawn from the nurseries by their mothers "on account of fretting," or because they contract an illness.

It seems inescapable that the cost in children's well-being is such that the policy of encouraging mothers to take full-time work and leave their young children in a nursery cannot be justified except on grounds of overriding national economic need. If, as seems probable, day nurseries consume as much labour as they free, or more, all basis for this policy disappears, and it would be in the national interest to pay a family allowance to the necessitous mother sufficient for her to undertake the important work of caring for her family herself instead of paying a heavy subsidy for her labour in industry.

This is not to say that day nurseries have not a part to play in the social scheme; there remains the need of helping many mothers and young children—hampered by health, temperament, home circumstances, and other causes—by provision for the care of young children out of the home. Foster homes, "good neighbour" schemes, nursery schools, part-time and full-time day nurseries, and resident nurseries can all play their part, but this is a large problem and an essentially different one from that of the wartime or industrial day nursery. In the one case the guiding principle is the well-being of the individual mother and child,

in the other the provision of more hands for industry. It behoves us to orientate our national policy on day nurseries in the light of the data available, and to obtain more factual information than at present exists as to the relative merits and demerits of various other methods of helping the overburdened mother of young children, or the young child needing other care than his mother's.

We know very little of the incidence of infection among children in residential nurseries, nursery schools, or part-time day nurseries; information which is essential when planning for child care. McLaughlin's cogent work compels attention in this field.

RESEARCH ON THE COMMON COLD

Little has been done in investigating the aetiology of the common cold since the work of Dochez and his collaborators in the early part of the last decade. This work fully confirmed the existence of a filtrable agent in nasal and throat washings from persons with colds which reproduces the disease in a substantial proportion of inoculated subjects, either chimpanzees¹ or human volunteers.² A further claim was made later that the virus could be cultivated in a medium containing chick embryo tissue cultures retaining their capacity to reproduce the disease throughout numerous transfers occupying several months; this observation is now regarded somewhat sceptically. It is noteworthy that during the period covered by this work Wilson Smith, Andrewes and Laidlaw³ discovered the transmissibility of epidemic influenza to the ferret. Research on influenza has proceeded steadily since that time whereas that on the common cold has lapsed into oblivion. The reasons for this contrast are clear: the possibility of transmission to an animal which is available reasonably cheaply and in large numbers is almost a *quæ non* for the thorough study of any virus disease. With this resource and the subsequent discovery of a simple method of titrating antibody the study of influenza has been enabled to cover a very wide field. Such methods have yet to be discovered and applied to the common cold.

It is to this problem that members of the staff of the Medical Research Council have been addressing themselves during the past year, and on May 2 the section of Epidemiology and State Medicine of the Royal Society of Medicine visited the Harvard Hospital, Salisbury to see the conditions under which transmission experiments are conducted, and to hear of the results hitherto obtained. A report of the formal proceedings will be found elsewhere in this issue (p. 650). This hospital was a gift to the British nation from the U.S.A. and was staffed during the war by the Harvard Research Unit, formed originally for the study of epidemic disease under war conditions in England. Now vested in the Ministry of Health, the hospital could be used for no purpose more appropriate or more consonant with its wartime tradition than the prosecution of the present research.

⁴ *Lancet* 1933 2: 66.

is extensive staff quarters have been readily converted into a series of completely self-contained units each housing a pair of volunteers, who are isolated from all human contact—except during the daily visit of a gowned and masked medical officer and matron—for a period of ten days. After three days' isolation they are inoculated intranasally with experimental material, and all the features of any cold which may result are carefully recorded. The meeting had been fixed for the penultimate day of an isolation period, and the visitors were therefore permitted to enter the quarters and interview their inmates. It was surprising and gratifying to hear that a visit to Salisbury for the purpose of serving as a human guinea-pig is looked upon by university students and others as a very enjoyable holiday: some volunteers have served twice and applied for a third admission when the prescribed interval of 6 months is over, and admissions are fully booked until the end of this year. It is very greatly to the credit of the organization that such *enthusiasm should have been produced*. The Harvard Hospital has no claim to beauty: it is situated on a bare and very bleak hill-top, and the huts, although commodious and warm, are plain and simply furnished. The volunteers can walk where they will in the surrounding country, they are liberally supplied with books and papers, and each unit has its radio and telephone. These amenities, and no doubt the sense of participation in an important scientific experiment, must explain the popularity of this peculiar type of holiday.

The fortnightly influx comprises 12 pairs of volunteers, of whom 2 pairs are inoculated with known positive material, and 2 pairs with plain broth. None of those in clinical charge knows the content of the different fluids used: hence there can be no possible bias in assessing results. The inclusion of these two types of control leaves only 8 pairs in each group for inoculation with unknown test material, and owing to the fact that fully active filtrates produce colds in only about one-half of inoculated subjects the resources of the team were likened by Andrewes to those of an experimentalist restricted to the use of about a dozen mice per month. Thus, in spite of the elaborate organization which has been set up, progress is likely to be slow. The main object in employing this laborious method is indeed to discover another which shall be more readily applicable. Progress is likely to be achieved only when the virus can be propagated in some other way than in the human volunteer or chimpanzee, and among methods which are being tested is propagation in the developing egg. As Andrewes pointed out, there are four different routes for inoculating eggs, and the stage of their development may also affect the result: moreover, of 60 different viruses which have been studied in this way, three-quarters have been successfully propagated. There are therefore good reasons for hoping that this much simplified technique may prove applicable, fortunately, normal egg fluids produced only one cold and 3 doubtful responses among 20 volunteers.

A good deal of basic information about the behaviour of the agent in active filtrates has already been obtained. An epidemic of colds at Harrow, where the secretions of about 20 affected boys were pooled, furnished a stock of

material which has been extensively used. The filtrate of this material retained its activity during storage at -76°C for over 4 months: it has also been determined that storage at -10°C is satisfactory for one month, and that activity is retained at $+4^{\circ}\text{C}$ for 3 days—a fact which enables material to be transported in an ordinary ice-box instead of being packed in carbon dioxide snow. The effect of dilution is not yet certain, and concentration has not been achieved. Particle size has been determined approximately by the use of graded filters, and the indications are that it is of the same order as that of influenza virus: since the number of volunteers tested with each filtrate other than that from the standard grade of filter was only 4, this conclusion must be regarded as only provisional. The incubation period of inoculation colds was most often 2 days but sometimes 1, 3, or more: they appear to have been mild and uncomplicated, possibly owing to the absence of accompanying bacterial infection. An interesting observation, not easily explained, is that the frequency of positive results from inoculation has been unrelated to the length of the interval which has elapsed since the subject's last natural cold. It is to be hoped that this does not boken the existence of numerous antigenically unrelated cold viruses.

The progress of this study, slow though it is likely to be, will be watched with much interest. It is reassuring to know that one of the principal lines of approach to the most banal and at the same time one of the most baffling problems in medicine is being pursued methodically by a full team of experts. Their anxiety that no early benefits should be expected is easily understandable: that progress in aetiological study does not necessarily afford any ready means of prevention or cure has been illustrated in the history of influenza. Whether any ultimately discovered means to this end will be on immunological, chemotherapeutic, or purely hygienic lines few would venture to predict. It is perhaps significant that the laboratory study of air disinfection by chemical and other means has also been transferred from Hampstead to the Harvard Hospital. Air sanitation is at least a practicable proceeding, the effects of which on respiratory infections are now being studied, and may well prove valuable.

SIR ALMROTH WRIGHT

By the death of Sir Almroth Wright British medicine has lost one of its most brilliant workers and one of its most picturesque characters. An account of his life is given in the obituary columns, here we shall attempt to appraise some of his contributions to medical science. Wright's father was a distinguished clergyman who had to educate a large family on a small income, so for economic reasons Almroth Wright had to win scholarships in such varied subjects as literature and law in order to pursue a university career. When he subsequently adopted medicine as his calling it was some time before he could decide which branch of medical science he should make his own. He worked at physiological problems with Wooldridge in Cambridge and with Ludwig in Leipzig, where he came

into contact with Pfeiffer, a leading figure in the then young science of bacteriology. It was as a physiologist that he went to Sydney, and although since his appointment as Professor of Pathology in the Army Medical School at Netley he has been called and known as a bacteriologist he remained to the end essentially a physiologist. Early in his career sleepless nights caused by a crying infant fed on cows' milk led him to apply his physiological knowledge, and by adding citrate he stopped the clotting of the milk in the child's stomach. He published his observation, but it was only many years after that citrated milk was advocated by paediatricians. He devised a method of measuring the coagulation time of the blood and by means of this estimated the effect of calcium salts, carbon dioxide, and other substances. He gave much time to the consideration of haemophilia, and wrote the chapter on this subject in Allbutt's *System of Medicine*. Another subject that interested him was acidosis, especially in scurvy, and later on in gas gangrene when this problem was presented to him in the war of 1914-18.

Almroth Wright's acceptance of the post at Netley must have marked his decision to give up physiology as a career. He soon became interested in the possibility of preventing bacterial infection by heat-killed vaccines. This was, of course, long after Pasteur had demonstrated that vaccines could make animals immune against bacterial disease, but Pasteur's vaccines were living attenuated cultures which, though suitable for immunizing sheep and cattle, were too dangerous for general use in man. Roux and others had shown that filtered cultures or dead cultures could produce immunity, but in these experiments they considered the fluid to be the active immunizing agent and not the bacteria, if present. Wright's original typhoid vaccine was a killed broth culture, but it was his conception that the active constituents of this vaccine were the dead bacteria. By blood tests of inoculated individuals he found that the vaccine stimulated the production of agglutinins and bactericidal substances. When he visited India as a member of the first Plague Commission he found opportunities of testing the efficacy of typhoid vaccine in some of the garrisons. These early observations convinced him that the vaccine did confer immunity. The vaccine was used to some extent in the South African War, but the resulting figures were very confused as at that time typhoid and paratyphoid fevers had not been properly differentiated. The statistical results in regard to typhoid vaccine in this campaign were the subject of considerable controversy, and in 1902 Wright left the Army Medical School and went to St Mary's Hospital, which at that time was seeking for a head of the pathological department. At St Mary's he founded his famous school of bacteriology.

For the next ten years he was preoccupied with the problem of vaccine therapy—the treatment of established infection by means of vaccines. With Douglas he developed the opsonic index and used it to control doses. The idea of vaccine therapy so controlled made a great appeal to doctors throughout the world, and for several years after 1905 workers from many countries came to Wright's laboratory at St Mary's to learn his methods. In 1912 Wright went to South Africa to investigate pneumonia in

the gold-mines, and he instituted a system of prophylactic vaccination which was continued for many years by Lister. In the war of 1914-18 Wright went to France as a consulting physician and set up a laboratory in the Casino at Boulogne, where he remained until the end of the war. He lived during these four years in the Rue Daunou, a few doors from the house in which he had, as a boy, stayed during the Franco-Prussian War. In Boulogne a number of his assistants from London joined him, and the team did much good work on the bacteriology and physiology of septic wounds and gas gangrene. It was then that extensive trial was made of the hypertonic salt treatment of septic wounds—a method which Wright had advocated many years before. This was based on the principle of drainage of the infected walls of a wound in contradistinction to the ordinary surgical drainage of the cavity of the wound. This method gained many adherents, and was the basis for the magnesium sulphate paste so commonly used in the casualty rooms. During these years Wright devised many interesting and beautiful methods of studying the function of leucocytes in relation to wound sepsis. He also introduced the method of immuno-transfusion. He had shown that the addition of a small dose of staphylococcus vaccine to human blood outside the body caused a rise in the non-specific bactericidal power of such blood, and in cases of severe sepsis patients were transfused with such vaccinated blood or with blood from an immunized donor. In the years after the war Wright continued this work on non-specific immunity and in the course of it evolved some useful methods—notably the slide-cell method for the evaluation of the bactericidal power of whole blood. This slide-cell method has been used for other purposes, especially by Fleming in his work on antiseptics and penicillin.

Almroth Wright's work and personality have had a profound influence on medical science. The success of typhoid vaccine stimulated research on other prophylactic vaccines—research which is still actively proceeding. The introduction of vaccine therapy provided another much-needed means of combating established infections, and it is a pity that this method has been abused. The discovery of the sulphonamides, and the development of antibiotics subsequent to the discovery of penicillin by Wright's pupil, Alexander Fleming, have made much of his work on vaccine therapy now a matter of academic interest only. Perhaps his greatest contribution has been his insistence that blood and other tests should be used to control therapeutic and preventive measures so that they may be used with intelligence. Bernard Shaw says elsewhere in this issue that men of science are usually rich in facts and poor in logic. Shaw's friend Almroth Wright was rich in both.

ASEPSIS IN SPINAL ANAESTHESIA

Since the earliest days of spinal anaesthesia a small proportion of patients given spinal anaesthetics have subsequently developed a type of meningitis which we discussed in these columns earlier this year.¹ In a number of recently reported cases in which meningitis has fol-

¹ *British Medical Journal* 1947 1 187 see also the article by Kremer *M. Jbid.*, 1945, 2 309

lowed a spinal anaesthetic the nature of the infection has not been such as to suggest the skin, either of the patient or of the operator, as its source. It has been due, almost without exception, to some sort of Gram-negative bacillus, either *Ps. pyocyanea* or a nondescript organism of the type commonly found in non-sterile water. Moreover, non-sterile water has been incriminated as its source, the needle and syringe used having been "dished up" in supposedly sterile water which was subsequently suspected or proved not to have been sterile. The clearest proof of this origin was obtained in the Sheffield series of cases described by Barrie², 11 out of 96 patients given spinal anaesthetics in one operating theatre developed meningitis, and the source of infection was found to be a defective Berkefeld filter supplying supposedly sterile water. A similar source was suspected in the two fatal cases of *Ps. pyocyanea* meningitis described by Evans³. Suggestive evidence of this possibility was furnished by the finding of the same organism in the cerebrospinal fluid of another patient without meningitis, this contamination being traced to a Winchester quart bottle of "sterile" distilled water. A bottle of sterile distilled water or saline cannot be depended on to remain sterile if it has once been opened.

A further series of cases due to the same type of infection, but of undiscovered origin, was recently described in this *Journal* by Vuylsteke⁴. Evans, in a further publication,⁵ and Garrod,⁶ who has recently reviewed this problem, make suggestions for a sterilization technique whereby such accidents can be avoided. Everything used for lumbar puncture, whether for spinal anaesthesia or for any other purpose, should be adequately sterilized by heat. Boiling will serve if necessary, dry heat is much to be preferred, and has the advantage that it can be applied at leisure, the apparatus then being always available for use when required. What should be avoided at all costs is some sort of chemical treatment, often itself unreliable, such as storage in spirit, and "dishing up" in water alleged to be sterile. This seemingly innocent liquid, harmless enough if introduced into any other part of the body, is fraught with danger.

IMMUNITY AFTER PENICILLIN

Is it possible for chemotherapy to be too successful? That is to say, may infection be overcome so exclusively by the chemotherapeutic agent alone that the normal defence mechanism need not function, that no immunity results, and a second attack may consequently follow? There are scattered items of clinical evidence suggesting this. Rantz, Boisvert, and Spink⁷ found that when patients with streptococcal sore throats were treated with penicillin antibody formation was deficient. Plummer and his colleagues,⁸ studying the same disease, found that a short course of treatment might be followed by a recurrence as severe as the original attack. This is evidently a question worthy and capable of experimental study, and P. E. Harrison⁹ has undertaken this with most illuminating results. Rabbits were inoculated intradermally with pneumococci, the so-called "dermal pneumonia" of Goodner being produced. This is a spreading inflammatory lesion of the skin proceeding to septicaemia and death, and has the great advantage

that the progress of the lesion can be directly observed. When penicillin treatment was begun in such animals four hours after inoculation the infection was aborted and no immunity whatever followed. This was tested by three methods: neither agglutinin nor protective antibody could be demonstrated in the animal's serum, and reinoculation produced a progressive and fatal infection. On the other hand, when treatment was begun 24 hours after inoculation the spread of infection was still checked and a high degree of immunity followed, as demonstrated by each of these methods. It is therefore evidently possible for penicillin given sufficiently early, to eliminate infection with little or no co-operation by the body defences: this is perhaps to be expected from the fact that its action on bacteria in the early phases of growth is rapidly bactericidal.

These observations are made doubly interesting by parallel tests with sulphapyridine, sulphadiazine, and sulphamerazine. These three drugs acted alike and with quite different results. The infection became more extensive and was more slowly brought under control, and the immune response was greatest when treatment was begun after four hours, when it was delayed for twenty-four hours the response was poor, even though the animal recovered. The explanation of this reversal of the finding resulting from penicillin treatment derives from the fact that the sulphonamides do not immediately check bacterial growth, this continues for a time, liberating further antigen, the quantity of which is apparently optimal for antibody response under the chosen conditions when treatment is begun early. Delay results in the formation of an excess of antigen, which neutralizes some of the antibody formed. That this is the true explanation was proved by demonstrating the specific soluble substance of the pneumococcus in the blood of rabbits treated with sulphapyridine at a late stage, and by showing that the injection of this substance depressed antibody formation. Closely comparable results were obtainable in mice, in which the sole criterion was resistance to reinoculation. When the primary peritoneal infection was treated with penicillin the maximum resistance to reinoculation was obtained when treatment had been begun after twelve or eighteen hours. With sulphadiazine resistance was maximal only when treatment had been begun at the time of inoculation or after two or four hours, with longer intervals the ensuing resistance steadily diminished.

It is of course possible that these findings, especially those concerning the sulphonamides, are not applicable to infections by all bacteria other than the pneumococcus. Even so it seems justifiable to conclude that there is nothing to lose, and probably everything to be gained, by beginning treatment with sulphonamides as early as possible. In the case of penicillin, on the other hand, there is at least a theoretical possibility that very early treatment may have a disadvantage. Whether any further evidence of deficient immunity following prompt penicillin treatment can be gleaned from clinical experience will be known only if this possibility is borne in mind.

Dr J. A. Brown, of Birmingham, has been elected for the term of five years a member of the General Medical Council as a direct representative in place of the late Sir Kaye Le Fleming. Dr Brown received 14,035 votes. Dr J. E. Outhwaite, 4,527, and Dr I. Rose, 695.

The next session of the General Medical Council will be open on Tuesday, June 3, at 2 p.m., when the President, Sir Herbert Lightfoot Eason, will take the chair.

THE USE, COST, AND PROVISION OF INFANT HEALTH HOSTELS

BY

J TUDOR LEWIS, MD, DPH

Medical Officer of Health County Borough of West Bromwich

It has previously been suggested that homes or hostels for mothers and their babies, which would bridge the gap between their discharge from maternity unit or hospital and their return to poor home conditions, should be a feature of the infant health services of the future (Lewis 1946). Such hostels, however, might have a more important role in counteracting unsatisfactory social conditions than that of mere post natal sanctuaries, and the subject clearly merits detailed thought. The local authority with which I was connected decided to set up a hostel, and the problem was examined from the local point of view. The results may be of general interest, because, apart from a review by the *Lancet* (1946) of convalescent-home facilities, this subject, especially as applied to the prevention of baby deaths and the promotion of infant health, does not appear to have received adequate objective treatment. For want of a better name, these hostels might be called infant health hostels and their purpose would be to combat the unsatisfactory social and environmental conditions that only too often interfere with the rearing of healthy infants.

It would not be difficult to write at length on how they would do this. In brief however they would be used to conserve the health and well being of the mother in the pre natal period and so prevent premature labour and reduce the incidence of prematurity, to act as the link between maternity units and hospitals and the home and thus save the infant from being exposed to unsatisfactory home conditions until it could stand them—the baby would in fact be "hardened off" in a hostel, to assist certain mothers by providing means by which for a period they could give all their attention to the baby, to help selected unmarried mothers and to give concentrated teaching in homecraft and baby care for most of the mothers admitted would need instruction in these important subjects.

To obtain the greatest benefit from an infant health hostel it could be necessary to ascertain the households where conditions were prejudicial to the healthy rearing of an infant, and to do this as early in the pregnancy as possible. We have called these households "observation households" for they should be kept under careful observation throughout the pregnancy, with a view to ameliorating the adverse conditions.

Cost of Infant Health Hostels

General—In setting up an infant health hostel there seem to be two principles to follow. (a) As the function of the hostel would be to give individual help to mothers beset with social difficulties and to impart concentrated instruction in homecraft and baby care, the proportion of staff to patients should be relatively high. (b) Although the babies admitted would not be under 2 or 3 weeks old there would still be a risk of the various forms of cross infection to which babies in institutions are always liable. If a serious infection were to break out, the smaller the unit the fewer would be the babies exposed. Therefore small units are to be preferred to large ones. The cost of a hostel would depend on its size and the staff necessary.

Size of the Hostel—What is the smallest unit that can be made an economical proposition? The nursing staff would have duties peculiar to this form of hostel for there would be little nursing as such and no need for night duty so long as some responsible person was available when necessary. In order to allow the nursing staff off-duty and holidays in accordance with the Rushcliffe recommendations a minimum of three would be needed. It is considered that a staff of three could run a hostel containing 10 to 12 mothers and babies and this would accord with principles (a) and (b) mentioned above. Considering the fairly heavy overhead charges to which a smaller hostel would be subject, the availability of suitable premises, and the scale of provision of hostels it is probable that a hostel of 10 to 12 beds and cots is the optimal size to aim at.

Staffing—The matron, or sister-in-charge, would be the key to the success of the hostel and must be carefully selected. She

should be an SRN possessing the SCM and the Health Visitor's Certificate and should have had practical experience of sociological and public health work. An active interest in and knowledge of baby-care and mothercraft should be an essential qualification. The other two nurses should have special knowledge and interest in young babies, should possess the SRN with experience of infants or should be State registered children's nurses. As in the case of the matron, an interest in the teaching of mothercraft would be essential. In view of the special qualifications required it might be possible to pay a small honorarium over and above the Rushcliffe scales in order to attract suitable people. It is anticipated that the mothers themselves would help in the domestic work of the lighter type, so there would be no need for a large domestic staff. One cook with two daily workers would be sufficient.

Capital Outlay—When new maternity units or hospitals are being built it might be possible to incorporate an infant health hostel in the main building thus reducing overhead charges, but for the present it would be necessary to adapt a large private house. Some guidance on what is required is given by Brodie (1946), who deals with homes for unmarried mothers but with minor modifications, her recommendations would apply to infant health hostels as also would those put forward by the National Council for the Unmarried Mother and her Child (1946). The large old-fashioned type of house would generally have to be used and it would need a good deal of alteration. A house of the size and type required could be purchased to day for about £5 000. Alterations might amount to £1 000 and equipment to £2 000—a capital outlay of about £8 000.

Yearly Expenditure—The following estimate of yearly expenditure is partly based on the running costs of a small maternity home of 12 beds, allowance having been made for the differences in the types of institution.

Salaries of nursing staff	£770
" " domestic staff	568
National insurance, rates, and insurance	100
Superannuation contribution	40
Printing and stationery	25
Cleaning materials painting repairs, renewals	100
Maintenance of patients and staff	400
Petty cash, sundries, telephone	30
Bedding drapery, earthenware goods	60
Light and fuel	300
Furniture replacements	50
Drugs and medicine	30
Gardening	300
Total	£2,773

Assuming that the 10 beds and cots were occupied throughout the year the approximate cost per mother and baby would be £5 a week.

Provision of Infant Health Hostels

The scale of provision of infant health hostels would vary according to the area. Where social conditions were very bad the need would be greatest, and this would usually be in industrial areas where housing conditions were bad and the social environment poor. Powers to set up infant health hostels are apparently given by Section 204 of the Public Health Act 1936.

The following gives some rough idea of the extent of the need. In 1945 of the 77 infant deaths investigated by Lewis and Blackwood (1946) it was estimated that a hostel might have helped to save 19 babies, in 1946 in a similar survey the estimated number was 16. It would however be the greatest mistake to consider only mortality, for there would be many babies whose lives might not be in acute danger but who would benefit in health and well-being from being admitted to a hostel. This problem is better considered in terms of infant health than of infant mortality. By so doing the net would be widely cast and in saving the lives of the few the many would benefit. In the ascertainment of observation households referred to above it was estimated that between July and December, 1946 25 mothers or mothers and babies would have benefited by admission to a hostel over the whole year this would mean that about 50 should have been admitted. During 1946 there were 61 infant deaths in the area so that according to these figures provision might be made for approximately one bed for each infant death.

Assuming that each mother and baby remained in the hostel for one month, 10 beds would provide accommodation for 120 cases a year. It is likely however, that many mothers would be unwilling or unable to stay that time, to offset this, some might stay longer and there might be an occasional long period case. If this approximate standard were adopted it is clear that only those authorities with over 100 infant deaths a year would find these hostels an economic proposition, unless joint hostels were set up or arrangements made for the admission of mothers and babies from adjoining local authorities.

There is virtually no well documented practical experience of the use of hostels for saving infant lives, for while many authorities have made arrangements for sending mothers and babies to convalescent homes, a definite attempt to combat the effects of adverse social conditions at all stages of foetal and infant life by the extensive use of a hostel has never, so far as can be ascertained, been made. It would, moreover, avail little to set up a hostel unless this were accompanied by the ascertainment of observation households as early in pregnancy as possible. Remembering the relatively high cost, both capital and revenue, of infant health hostels and that they must at first be experimental, it is evident that no extensive provision on the scale of one bed per infant death could be considered, but as an experiment in social and preventive medicine their use in selected areas may rightly be advocated. They can do no harm, they are certain to do some good, they may prove to be a means of saving many infant lives. To achieve this any reasonable expenditure of public money would be justifiable.

Summary

The uses of infant health hostels as a means of combating adverse social conditions are set out, the functions of hostels are referred to, and the indications for admitting mothers and babies are considered.

The optimal size of a hostel is 10 to 12 beds and cots. Staffing is dealt with and an estimate of the capital and revenue expenditure made.

The need for hostels is assessed. It is suggested that provision might be made on the scale of approximately one bed and cot per infant death per year. Until, however, the uses and value of infant health hostels are more clearly defined, they should in the first instance be experimental, and be set up in those areas where the infant mortality rate is high, as an organized attempt to reduce it.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS

The Society held its spring meeting in Lisbon on April 10 and 11 under the presidency of Sir Hugh Cairns. The meeting was arranged to pay tribute to Prof Egas Moniz for his pioneer work. It was he who introduced arteriography (in 1927), which was used in cerebral work first. The leucotomy operation for certain mental disorders was a later conception and was first performed by Prof Lima in 1935. The visitors, including members from several European countries, were welcomed by Prof Flores of the Lisbon Faculty of Medicine, Prof Moniz's successor in the Chair of Neurology.

Prof Moniz spoke on thrombosis of the internal carotid and its branches and on the interpretation of cerebral angiograms, especially the striking difference in circulation rate through the internal and external carotid systems. Prof Lima described the diagnosis of subdural haematomas by arteriography. Prof Furtado and Dr Marques spoke about the Arnold Chiari malformation, Prof da Costa on the neuroblastomas, and Prof Fernandes on leucotomy. The technique of carotid arteriography was demonstrated by Dr Imaginário and of aortic arteriography by Dr dos Santos. An excellent exhibition of cerebral angiograms included the early experimental procedures and instruments used for them, now of interest historically. Several communications, mostly relating to Prof Moniz's work, were given by the visitors including Mr Norman Dott's on intracranial aneurysms, and Prof Geoffrey Jefferson's on frontal lobectomy.

Reports of Societies

COMMON COLD RESEARCH UNIT

INTERIM REPORT ON A TRANSMISSION EXPERIMENT

A meeting of the Epidemiology and State Medicine Section of the Royal Society of Medicine was held on May 2 at the Common Cold Research Unit, Harvard Hospital Salisbury, where for about a year, under the auspices of the Medical Research Council and the Ministry of Health an investigation into the aetiology of the common cold has been undertaken. A succession of groups of volunteers have accepted isolation for a fortnight at a time in order that they might be tested with the common cold virus. The conditions and the outcome of the research so far are described in this report and are the subject of a leading article at p 645.

Members of the Section and others, who attended in large numbers, were received by the staff of the unit. They visited the isolation quarters—flats—of the volunteers and the hygiene laboratory, and then assembled in the lecture hall where a film produced by the Central Office of Information was projected. Dr H J PARRISH who presided, said that the common cold was responsible for the loss of 40 million man days a year, yet he believed this was the first time the Section had had a discussion on the subject.

History of Harvard Hospital

Dr W H BRADLEY gave an account of the origin of the hospital and of the unit. At about the time of Dunkirk the Harvard University planned to send to this country a group of field and laboratory workers to assist in the control of epidemics which were expected to arise. The Harvard unit grew into a team of more than 100 doctors and others. 22 buildings, prefabricated in the United States, were transported to this country and erected on a site near Salisbury secured and prepared by the Ministry of Health, and the hospital was formally opened in September, 1941. In selecting the location regard was paid to the suitability of the place for epidemiological studies of the detailed and intimate type called "clinical epidemiology." This part of Wiltshire had for the epidemiologist much the same kind of advantages as the 'Pickles' country of Wensleydale. The hospital was for a while perhaps overburdened with beds (125), it became a E.M.S. hospital for both civil and military cases of communicable diseases, and no group of patients suffering from such diseases ever before received so much investigation and therapy. The course of the war unfortunately prevented the full benefit of the studies from being reaped, but some of the work was published in the reports for the war years of the Chief Medical Officer of the Ministry. With America's entrance into the war the hospital passed into the hands of the U.S. Army, and became the central laboratory for the American Army Medical Corps in the European theatre. The laboratories were extended and adapted for special purposes, and research units were established—one, for example for the study of rickettsial disease. The place rapidly acquired a reputation as one of the foremost laboratories devoted to preventive medicine. With the invasion of France in 1944 the central laboratory was transferred to the Pasteur Institute in Paris, and with the cessation of hostilities in May, 1945, the American military authorities finally withdrew, though the place remained an important link between the United States and Great Britain and between Harvard University and its Faculty of Medicine on the one hand and the Ministry of Health and the Medical Research Council on the other.

The hospital was built specifically as an institute for the study of communicable diseases, and it was decided to adapt it to the purposes of a long term research into the aetiology and transmission of the common cold. The staff and personnel house was converted into flats for the use of volunteers, and the staff of the unit and of some of the laboratories was housed in what had previously been the wards. The work was started in May, 1946, on plans which were first discussed less than six months previously.

It was seldom clear how projects of this kind began, but the first knowledge of it was a memorandum by Dr C H Andrewes.

suggesting that the advances made in virus work might now be applied to the study of the common cold, and this limited objective was adopted. The plan was to discover a method of studying the virus, which could not at present be handled in the laboratory by existing techniques. Human volunteers—the justifiability of using them was agreed to after much debate—were employed as indicators of the presence of common-cold producing agents, and it was hoped that eventually a substitute would be found for them. Colleagues were always telling him that there was much else to be done in the study of the common cold. An attempt had been made to assess the priority of the various researches proposed, and they must not bite off more than they could chew. Many extensions of the present research would occur to all of them, and these would be explored in due course.

The Plan of Research

Dr C. H. ANDREWES said that it had been known for more than thirty years that a cold could be transmitted from one person to another by means of bacteria-free filtrates, and that such colds were transmissible in series. It had also long been known that chimpanzees—but no other kind of animal—could also be infected. A claim to have cultivated the virus in a tissue culture medium had not been confirmed. The most likely working hypothesis was that the filtrable agent which would produce transmissible colds in series was a virus, but not much was known of its properties because of the clumsy way in which it was necessary to study it. The primary objective was to find some substitute for the human volunteer, some laboratory method by which to recognize the presence of the virus. They were attempting, first of all, to adapt to the study of the cold a number of virus techniques which had been developed during the last fifteen years. They were concentrating attempts to grow the virus in fertile eggs, because about 60 different viruses had been studied in this way, and in about 75% success had been attained by one or other technique, so that there was a three to one chance of finding some technique of growing viruses in eggs. They tried to grow the agent in the egg, and then they had to use the human volunteer in order to decide whether the experiment was getting them anywhere.

It was not expected to solve this problem quickly. A succession of volunteers would be required for a period of years, and therefore the conditions must be attractive. The first volunteers were students during university vacations, and the idea was so popular that some of the students came again after a six months' interval. But it was necessary to get more volunteers, and on an appeal being made to the public 2,000 applications were received. It was thought that solitary confinement would be a deterrent and therefore the volunteers were housed in pairs. They were given every possible freedom consistent with carrying out the experiment. If they had been required to wear wet socks and sit in draughts their noses might have run more freely, but the flow of volunteers would have dried up. The volunteers were kept for three days before receiving inoculation in case they had arrived already incubating a cold. It had been suggested, particularly by recent work in America, that there might be some infections simulating the common cold but with a much longer incubation period than two or three days. That was a serious criticism of the technique at present employed in the unit, but they were following it with their eyes open, and they hoped that if there were any diseases simulating the common cold they would not be led astray. If they had a longer incubation period—a fortnight or more to allow for the mild form of atypical pneumonia which simulated colds—they would halve the speed of the work.

The volunteers were isolated on the assumption that they were likely to pick up colds by contact with other people. No stringent precautions had been taken to prevent the infective agent reaching the volunteers by means of inanimate objects such as newspapers or milk bottles, it was not believed that these were serious sources of danger. The system of controls was such that they would get some indication if these precautions were inadequate. A full blown cold was not difficult to detect clinically, but there were bound to be many intermediate conditions, mild sniffles, and so on. To avoid any bias in any trial, certain volunteers received normal egg fluids or other material known not to contain cold virus, and nobody but the laboratory worker knew what was given to any volunteer, each person receiving the material from a numbered bottle.

Twenty-four people—twelve pairs—were taken at each trial. Two of the pairs received a negative control material, and, in most trials, two a positive control material. This left eight pairs for the material it was desired to test. Something like 50% of people were resistant to the material, so that to test any one material it was necessary to take at least four subjects, two pairs, as the minimum. Their speed of progress was roughly that of the laboratory worker who was supplied with twelve mice a month. There must be no disappointment if progress was rather slow. Other angles of approach were possible in the future—a study of the individual resistance of the patient, epidemiological studies, air hygiene, climatology and orthodox bacteriology, but they felt that orthodox bacteriology had been studied rather more than other aspects.

Routine of Experiments

Dr D. K. M. CHALMERS, who has had the actual handling of the volunteers at the unit, said that the task was first to provide the bacteriologist with human subjects in isolation under such standard conditions as were practicable, and then to make the clinical assessment on which the results of the experiment were based. He described the recruitment, first of undergraduates, then members of the Red Cross, workers from certain selected industries, and finally the general public. The age limits were 18 to 40—after school age and before the setting in of the chronic catarrhal conditions of later life. People with asthma, hay fever, sinusitis, or a history of pulmonary tuberculosis were excluded. Conditions had to be as attractive as possible, not to spoil the volunteers but to retain their good will. There was almost complete freedom, except that they must not mix with other people. A distance of 30 ft (9 m) was regarded as beyond the reach of cross-infection. Each trial lasted for ten days. After a communal lunch on arrival the volunteers were given a preliminary talk, underwent a medical examination of life insurance standard (but including an x-ray examination of the chest), and then went into quarantine for seventy-two hours to exclude incubating colds. Materials believed to contain virus or materials known not to contain virus were instilled into the nose, 0.5 ml into each nostril, with the subject maintaining the supine position for two minutes, followed by the prone position for one minute. Neither the subject nor the doctor knew whether the one or the other material was used in a particular instance.

Clinical assessment began on the fourth day, and continued throughout the remainder of the trial. The matron recorded pulse and temperature daily on a chart. The criteria of each assessment were subjective and objective. Each volunteer reported any symptoms he or she might have. The appearance of the fauces was noted, and especially the evidence of what could be blown out of the nose on to the handkerchief. It might well be that the experimental cold induced in the unit was not the same thing clinically as the cold seen outside. For one thing, there should be less secondary infection. But the induced colds varied from the doubtful abortive cold to the abundant rhinitis. The incubation period was from twenty-four hours to five or six days. The Americans said that they could distinguish two types—one with a short incubation period of from twenty-four to forty-eight hours, and the other with a much longer period of from five to nine days. In the former the symptoms of running nose and coryza predominated, in the latter, sore throat and constitutional symptoms. This suggested that there might be more than one virus associated with the cold. In conclusion he stressed the fact that both the administrative arrangements for the volunteers and the methods for excluding extraneous infection were still in the experimental stage, but they were learning as they went along.

Interim Report

Dr F. FULTON gave an interim report on the results of the transmission experiments. He described the method whereby the material was collected from the subject, sent to the laboratory and centrifuged. The filtrate, which was cleared of all bacteria, was then stored. The first problem was to determine whether it was possible to go on storing the material indefinitely and still maintain the life of the virus. It had been shown that the filtrate could be stored for at least four and a half months at -76°C . He showed tables indicating activity at this and at other temperatures. At ordinary icebox tempera-

re + 4 C, activity persisted for three days. An attempt was also made to determine the size of the agent responsible. The washings could contain substances of quite different sizes. It could not be said that the lower limit of size was fixed, the upper limit was fixed, but not the lower. The most common incubation period was two to three days, but a few colds developed after five or six days, which was the limit of the period of observation; therefore the present observation period was not ideal though the majority of colds would probably exhibit themselves within that time. It did not appear to signify whether the subject had had a cold during the previous month or had had no cold for six months. 'The only thing we are certain about is that we have got some agent in the common cold filtrates which will induce colds in a percentage of the people, all the other results are tentative.'

Questions

Dr PARRISH said they were not yet at 'the end of the beginning of this investigation. The suggestion that women were much more susceptible to colds than men might be followed up, also an investigation might be undertaken into the determining factors in colds—an infection plus, probably, some depression of resistance due to climate, under-nourishment, or some other factor.

Asked whether any complement fixation tests had been tried, Dr ANDREWES said that this had been kept in mind, but it was suspected that they would have to get the virus present and growing in greater concentration before that could be successful.

Did the particle size exclude the possibility of a filter-passing bacterium? Dr FULTON replied that the filtrates had been cultivated under conditions which would be likely to grow these agents, and no growth had been observed at all.

Dr ANDREWES in reply to a further question, said that no intensive studies had been made on secondary infection because most of the laboratory work had been done at the National Institute for Medical Research, Hampstead, and the clinical work at Salisbury, but now that there was a bacteriologist on the spot it would be possible to do more along that line. No attempt had been made to induce secondary infections.

A questioner wished to know whether the filtrates had been stained and smeared and small bodies seen. There was a possibility of the use of fluorescent dyes in this connexion. Dr FULTON said that that had not been tried. The electron microscope or ultra-microscope, said Dr ANDREWES had not been applied to the filtrates because the use of these instruments required considerable concentration of the material.

Dr CHALMERS in reply to a question as to whether one of the pair of volunteers who had a cold could pass it on to his partner in the flat, said that if a volunteer resisted the artificial cold given to him, and his partner took it, the former would resist also cross infection. On the other hand, people who developed colds during the period of quarantine frequently conveyed such colds to their partners. He explained that each pair was given the same material.

In reply to Dr J A H Brincker, Dr CHALMERS said that it was always recorded whether the volunteer had undergone tonsil or adenoid operations, but no correlation had yet been worked out. In further answer Dr Chalmers said that only in two cases had a volunteer developed tonsillitis, and in one case bronchitis, which lasted for about a week. As for precautions against infection conveyed by those who handled food for the volunteers, he said that any member of the small domestic staff who developed a cold reported it at once. The handling of food was very carefully supervised.

Dr SUTHERLAND said that he understood that during these experiments only one person had had to go to bed with the cold, and he only for a short time, which rather suggested that the type of cold was not comparable with that experienced by the ordinary patient. Dr CHALMERS replied that the people were always asked the date of their previous cold and how many colds they customarily had in a year, and whether they had had to stop work and go to bed, and the answer to the last question was invariably "No."

Dr ANDREWES said that it was possible that the cold encountered in the outside world was a mixture of a virus and a bacterial infection, while in the unit a pure virus infection was given. The people had less chance of picking up secondary

organisms from one companion in the unit than from many with a number of people. The volunteers were given a card and asked to describe what happened after their to ordinary life. Frequently those who while in the unit had developed a cold which had cleared up developed a worse cold a day or two after resuming contact with the outside world.

Dr ASHWORTH UNDERWOOD asked whether consideration had been given to the extension of the time of observation to seventeen days or three weeks, especially in view of the small number of samples. Dr ANDREWES said that the time would have to be a number of weeks for convenience of administration. If one or two odd colds were found turning up when they should not, he did not think it would upset the experiment. They would have to tighten up their regulations and extend the period of observation.

Dr CHALMERS, in reply to a question as to whether particulars of menstruation were taken in the case of the women volunteers in view of the frequency with which the nasal mucosa became congested just before or during the menstrual period, said that such particulars were recorded, but so far there had been no opportunity to work them out.

Dr ANDREWES who was asked whether it would be possible during the incubation period to get some information as to the flora of the nose, said that this was possible but hardly worthwhile, because there was such an enormous literature of bacteriology in relation to the nose and very little had come out of it.

Asked about work in America, Dr ANDREWES said that his teams were working there on lines similar to their own, one of them was using as volunteers prisoners in a reformatory.

Dr W BUTLER asked whether those concerned were satisfied that the whole clinical field of the common cold was embraced. If the experiment were reversed and the virus excluded, would there not be a certain number who would get a common cold though perhaps distinguishable in some respects from the cold which were virus-produced? Dr ANDREWES replied that he was constantly talking to people who spoke of pneumococcal and bacterial colds. Some colds might be caused by such organisms, but he would like to have an opportunity of studying such colds in order to learn whether it was possible to reproduce them with cultures. It would be interesting to take one of these pneumococcal colds and use a filter and see whether the cold could be reproduced with the filtrate.

Correspondence

Endocrines in Gynaecology

SIR—I shall be glad of an opportunity of replying to the interesting and instructive letters from your correspondent during the past few weeks. The emphasis has been laid chief on the principle of receptor substances or the specific sensitivity of the various tissues to the action of individual hormones having been recognized for many years. This is well illustrated by the letters of Dr G I M Swyer, Dr S L Simpson, Dr Raymond Greene and others. I did not wish to suggest that the receptor mechanism was a new concept. It is the basis of much of the maintenance of physiological processes of the body, including the intricacies of immunology.

In my address published in the *Journal of Jan 18* (p 79) I said, "I have *seldom* seen it [the idea of receptors] mentioned and *never* considered, in therapeutics." The italics should have been used in the original publication. While agreeing with your correspondents that the conception of receptors is not new yet I still feel that, compared with the enormous amount of therapeutic energy devoted to the activating hormone relatively little or no consideration has been given to laboratory or clinical research on the responsiveness of the organs we wish to treat. The important point is not so much the recognition of the principle of tissue receptivity but how far the idea has provided a basis for research into its tangible reality. So far very little.

I confess that I cannot understand Dr Swyer's appeal (Feb 1 p 98) not to "complicate" the issue by adding the notion of receptor substances. All biological processes are complicated, but this should be, and has already been, a stimu-

Ribena therapy in infective diseases

In all acute febrile illnesses the bodily demand for vitamin C is greatly increased and should be met by an extra-dietary supply. Extensive experimental work has led to the view that the vitamin plays a vital rôle in the defence mechanisms of the body, though its exact mode of action has not yet been elucidated. In diphtheria, scarlet fever, rheumatic fever and puerperal fever, Ribena is particularly indicated, its glucose content being of advantage as a cardiac stimulant.

Ribena Blackcurrant Syrup is also particularly apposite to conditions of high temperature since it can be administered, suitably diluted, as a cooling drink.

With its standardised content of not less than 20 mg ascorbic acid per fluid ounce, the physician can be assured of a satisfactory vitamin C intake, plus the lesser known factors associated with the vitamin in its natural form.

to reduce
infant skin
irritations

Johnson's

BABY LOTION

ANTISEPTIC

leaves a discontinuous film

LABORATORY and clinical tests indicate that Johnson's new Baby Lotion is an important step forward in infant skin care. It is a white antiseptic lotion for cleansing and soothing that leaves a discontinuous oil film on the skin. This is because Baby Lotion is an oil in water emulsion homogenised under pressure to provide the extreme dispersion of oil in micron size globules. This property contributes to normal skin functioning, permitting normal heat radiation and allowing perspiration to escape readily. Johnson's Baby Lotion therefore helps to prevent heat rash and skin irritations.

*designed by a
gynaecologist...*

1934 saw the first adaptation of the principle of the surgical tampon to the absorption of the menstrual flow. Designed by a practising Doctor, Tampax not only won favour with women themselves, but gained the approval of gynaecologists for its alleviation of mental stress and physical discomfort and its guarantee of hygiene and safety—the latter ensured by the patent stitching process which

makes disintegration impossible. Throughout the world today Tampax is recognised as the best form of modern sanitary protection.

If you are not receiving your copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to Medical Inquiries, Tampax Ltd, 110 Lymington St., London, S.W.1

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the tampon at aperture would cause difficulty in insertion and withdrawal.

rather than a deterrent to research. Some failure in physiological advance fifty and more years ago was due to the passion for simplifying processes which we know now to be of the most amazing complexity. Renal excretion and carbohydrate metabolism are two of innumerable examples. And now the clinical failure of endocrine treatment implies that until the problem becomes more "complicated" for the physiologist we shall make no further progress from our present static position. "Static" is the word. For some years we have achieved no real advance in this branch of endocrinology.

Prof. E. A. Doisy, of St. Louis University, has written personally to point out that it was the late Dr. Edgar Allen who concluded that cornification of the vagina is due to a hormone found in the Graafian follicle of the ovary. The important work of Stockard and Papanicolaou undoubtedly influenced the pioneer work on the ovarian hormones which was done by Dr. Allen and Prof. Doisy.

While discussing the general difficulties of hormone therapy I dwelt upon the paramount importance of the nervous factor in the control of the hormone system in man, and thus I agree strongly with Mr. Everard Williams when he draws attention (Feb. 8, p. 234) to the overriding influence of emotional disturbances acting through the nervous system in producing symptomatic effects in the various end organs. It is almost certain that emotion such as the fear and fright of the air raids acted both through the pituitary and directly on the end organs through their nervous supply. In addition to Mr. Williams's examples of menstrual troubles I remember the remarkable effect of the near-by bursting bomb in starting the immediate onset of premature labour.

Some correspondents have discussed details of treatment. Dr. Donald Fraser (p. 234) makes a plea for progesterone in metropathia. I quoted the work of Dr. Scowen in support of this treatment and also success following the use of testosterone. It is nevertheless true that many cases suffer relapses, which will compel us ultimately to treat these patients by x-rays or hysterectomy. Dr. Raymond Greene's remarkable case of cure of eunuchism (March 8, p. 311), as proved by a subsequent pregnancy, is of great interest, and an encouragement to treat similar and less well established cases on the lines he describes.

But perhaps the best summing up of the difficulties of endocrine therapy is given by Dr. A. P. Cawadias (March 22, p. 390) when he describes the disorder not as a separate disease of one or more of the six chief glands but as a pathological "complex" based upon irregular function of the whole psychosomatic system, including the endocrine glands, and all in relation to environmental factors. Through all your correspondents' letters can be traced agreement, with varying emphasis, on some fundamental points. The idea of cell receptors in the end-organs is by no means new, but it has not yet been exploited by researches which might enable us to expand our resources in treatment.

Finally the patient apparently suffering from an endocrine disorder such as metropathia, amenorrhoea, and many others must be regarded not as one suffering from a terminal symptom but as a victim of genetic liability and environmental stress. The second of these will include such varied factors as nutrition, human relationships, conditions of work and play—indeed all the manifold impacts inherent in our modern and troubled civilization—I am, etc.,

London W 1

ALECK BOURNE

d-Tubocurarine in Electric Convulsion Therapy

SIR—I have read with interest the articles on the use of d-tubocurarine in electric convulsion therapy, and in view of the fact that Drs. J. A. Hobson and Frederick Prescott (April 5, p. 448) state that they intend to adopt this method "as a routine" I should like to make some comment on this. Whereas one cannot fail to be impressed by the use of this method in a few of the cases mentioned I consider that it is high time that some of the nonsense written about the dangers of ECT should be contradicted by those of us who use this form of therapy on a large scale. In this hospital alone an average of 400 convulsions are administered each week, and in a period of six years well over 100,000 treatments have been carried out without major accident. It should be noted that some of the patients treated were over 75 years of age.

The occurrence of fractures and dislocations is, in my opinion, to be attributed to faulty technique rather than to the method itself, and I consider that the use of restraint by nurses is to be strongly deprecated, as it most definitely introduces a factor which may be fraught with danger. Figure 1 in Dr. Hobson's article (p. 447) illustrates this point. It should be quite unnecessary for anyone to actively restrain a patient during an electrically induced convulsion unless, of course, in the very rare instance where a patient may be in danger of falling out of bed.

The first case described by Drs. A. Gillis and D. D. Webster (p. 451) is of great interest, but it is unfortunate that the authors do not state the exact time which had elapsed between the receipt of injury and the commencement of ECT. I can see no reason why ECT should have been contraindicated in the second case in the absence of vertebral injury, as severe back pain is not a very uncommon symptom but one which usually disappears during the course of treatment.

In making these criticisms I do not wish to detract in any way from the value of d-tubocurarine in a few cases, but, as the authors admit, it calls for skilled technique, and as the method itself is not without danger it should surely be used with the greatest discrimination—I am, etc.,

St. James Hospital, Portsmouth

W. LIDDELL MILLIGAN

Phaeochromocytoma

SIR—Are not the symptoms of phaeochromocytoma of the adrenal medulla, described in two interesting articles in the *Journal* of April 26 (pp. 563 and 564), suggestive of those of the so-called "anxiety crisis" writ large? As a victim of these crises, the full nature of which can be understood only by those who undergo them, I have the most profound sympathy with the young woman who "was 'nervous' and anxious to demonstrate that her disease was not functional."

No reasonable person would be anxious to demonstrate that his symptoms had their origin in so grave a condition as a suprarenal tumour, but neither does a reasonable person find it satisfying to be told that his prostrating attacks are purely functional, due to some underlying worry of which he has never been conscious. His own rational brain gives him all sorts of reasoned assurances as his bout develops, but his instinctive feelings are filled with the most positive certainty of his imminent exitus and are suffused with fear, not the fear which he may have felt when exposed to real and obvious danger such as heavy air-raids, but the horrible paralysing fear which arises in the worst type of nightmare and which strips from him the last vestige of his self-respect.

My own attacks have beset me for more than a dozen years. During the intervals between them it is easy to tell myself that if their origin was serious I should not have continued to survive yet each bad one finds me as vulnerable as any of its forerunners.

As I grow older in practice I find myself more and more convinced that much illness which we now glibly dub "nervous" and hand over to the psychiatrists will be found to have a purely physical basis, which may well have a quite trivial importance when compared with its effect on the psyche. If the day ever comes when necropsy by a skilled pathologist is obligatory for everyone, it will probably bring an enormous acceleration in medical learning and it is at least possible that our present unsatisfactory fumbling with the human mind will be diverted into more useful channels.

In view of the personal nature of this letter may I have your leave to sign myself

The Adrenal Medulla and Hyperpnea

SIR,—In regard to the annotation on the adrenal medulla and hyperpnea (April 26, p. 572), we have repeatedly tried to discover whether the adrenaline content in the blood is raised in hypertony, but without success. But the following experiments which O. Weiss and I performed many years ago are significant.

Adrenaline was injected into a cat and arterial pressure taken by kymograph. There was a very pronounced rise of pressure but lasting only a moment. After the arterial pressure in this cat had returned to normal, blood was taken from it and injected in another cat. The latter animal produced the same

adrenaline reaction as the first. Thus it has been established that although the adrenaline content of the blood in the first attack was still abnormally high, after an initial rise of pressure it did not further affect the blood pressure level. But after severing the nerves from the blood vessels of the ear, the adrenaline effect lasted for hours. It is quite clear that the vasoconstrictors and vasodilators counteract any factor which tends to produce abnormal pressure. The level of pressure is conditioned by the requirements of the body and not by abnormal substances in the blood such as adrenaline or renin which tend to raise the pressure. This is the reason why it is so very difficult either to raise or to lower arterial pressure for any length of time—I am, etc.

Liverpool

I HARRIS

The Revolution in Anaesthesia

SIR,—Dr John Halton (April 19, p. 543) has painted a fanciful picture of the benefits conferred by curare on the inefficient anaesthetist. No one will gainsay that curare is, in certain circumstances, of great help to surgeons and anaesthetists, but the patient is the most important person in the operating theatre and the benefits conferred on the patient are more questionable. When anaesthetized by ordinary methods he has at least a reasonable expectation of recovering consciousness and of a convalescence free from complications. In a series of over 50 gastrectomies relaxed with curare which have come under my observation the incidence of collapse of the lung base confirmed by X-ray, is 20%, and this high figure has been confirmed by other observers. Bleeding with curare is often considerable and I have been asked by a surgical colleague to refrain from using it for this reason alone. Several deaths have been reported from regurgitation of stomach contents into the lungs. Relaxation can be carried a little too far.

The introduction of a new drug is always accompanied by a pendulum-like swing of enthusiasm followed by a swing in the reverse direction, after which the true position of the drug in medicine is determined. I suggest that the time has come to cry halt and reflect on the lethal possibilities of this very potent drug. Dr Halton has spoken of a revolution in anaesthesia, but history contains many examples of revolutions which have not proved beneficial—I am, etc.,

London W 1

MASSEY DAWKINS

SIR,—Dr John Halton's masterly exposition on the use and abuse of modern anaesthetic technique (April 19, p. 543) will be greeted with acclamation by every anaesthetist who understands the physiology of respiration and is thoroughly conversant with the action of the drugs and agents which he uses. My only comment is that he made some omissions in his true and vivid picture; he made no mention of the final 'shot of tubarine' to enable the peritoneum to be closed and to guarantee the production of "the twilight of that half-world known as 'recovering from the anaesthetic,' which justifies matrons of nursing homes pressing for the abolition of curare" (*Journal* Jan 18, p. 111, Feb 8, p. 234).

He rightly stresses, but no one could overstress the need for maintaining adequate tidal exchange and the avoidance of anoxia; he omits to mention the danger of an insidious build-up of carbon dioxide responsible for the production of so called "cyclo shock" (*Anesthesiology* 1947, 8, 15). Surely when the respiratory centre is depressed by opiates, barbiturates, and what you will in the way of anaesthetic agents and has its peripheral response stultified by intercostal paralysis, possibly combined with diaphragmatic paralysis or paresis, the final physiological insult is to expose it to excess of carbon dioxide by cutting out the absorber or adding from a cylinder.

No absorber is too efficient, the danger of losing the 'Bohr effect' and producing the 'acarbia' spoken of by Yandell Henderson is a relic of the past and could only be produced now by the most energetic hyperventilators, who could, no doubt, also squash your alveolar capillaries flat and kill you with a chest full of oxygen. Equally nefarious is the practice of relying primarily in times of crisis on alleged antidotes such as "prostagmin," picrotoxin, "coramine" etc. rather than maintaining normal or near normal oxygen-carbon dioxide balance.

As one of the first to suggest that the advent of curare cast doubts on the theories of Crile (*Proc Roy Soc Med* 1946 39,

410) may I join with Dr Halton in his hope that the rational use of curare will make it a milestone in anaesthesia rather than that by abuse it should become a tombstone—I am, etc.,

Aylesbury

H W LOFTUS DALI

BCG Vaccination by International Exchange

SIR,—The Scandinavian countries, with their many years' wealth of BCG experience are now exporting not only advice but also personnel. Dr Konrad Birkhaug, who was in charge of the BCG laboratory in Bergen before and during the war has gone to the USA, where the State Health Department has borrowed his services. In Denmark the Danish Red Cross has a scheme for BCG teams, each consisting of a doctor two nurses, and a secretary, to go to Warsaw, Budapest, and Rendsburg to vaccinate their populations, children first. What about a loan of Scandinavian experts to England? Assuming that BCG vaccination is not an all-British watertight compartment I would suggest that the Ministry of Health or the National Association for the Prevention of Tuberculosis sends a 'come over and help us' call to their opposite numbers in one of the Scandinavian countries, say Sweden—I am, etc.,

Sunnfjord Norway

CLAUDE LILLINGSTON

Acid Drinks and Sulphonamide Therapy

SIR,—The danger of renal complications during sulphonamide therapy and the importance of giving extra fluids to patients receiving these drugs are universally recognized, but the necessity for avoiding acid fluids and maintaining alkalinity of the urine have not been given the same prominence in the literature.

The M.R.C. War Memo No. 10 (Medical Use of Sulphonamides) states that 30–80% of the total dosage can be recovered from the urine either as the sulphonamide itself or as its acetyl derivative. The following table, also taken from the Memo, shows the solubilities of some of the sulphonamides and of their acetyl derivatives in both acid and alkaline urine and from this I have worked out the daily output of urine necessary to hold 3 g. of each of the sulphonamides in solution—that is, 50% of an average daily dose.

	Solubility in Urine (mg./100 ml.)		Volume of Urine Needed to Dissolve 3 g.	
	Acid	Alkaline	Acid	Alkaline
Sulphathiazole	102	859	3 000 ml.	350 ml.
Acetyl sulphathiazole	10	265	30 000	1 200
Sulphadiazine	17	187	17 500	1 500
Acetyl sulphadiazine	50	229	6 000	1 300
Sulphamezathine	130	335	2 300	900
Acetyl sulphamezathine	86	216	3 500	1 400
Sulphamerazine	38	209	8 000	1 400
Acetyl sulphamerazine	78	227	3 800	1 300

This table shows that with an average daily output of 1,500 ml. of the urine must be alkaline, otherwise part of the sulphonamide excreted will be thrown out of solution.

In most hospitals extra fluids are supplied in the form of imperial drink, lemonade or orangeade. These substances are highly acid, as the following rough experiment shows. Samples were taken from the patients' jugs in the wards and neutralized with sodium bicarbonate. The quantity of bicarbonate required to neutralize 1 oz. (28 ml.) of each fluid was as follows:

Orangeade	15 gr. (1 g.) of bicarbonate
Lemonade	15 gr. "
Imperial drink	11 gr. (0.72 g.) "

Thus with a daily intake of only 3 pints (1.7 l.) of the fluids in question the amount of bicarbonate required to neutralize it works out at 900 gr. (60 g.) for lemonade and orangeade and 660 gr. (44 g.) for imperial drink—this before alkalimination of the patient can begin. The usual routine practice of giving a dose of alkali with the tablets can only serve to neutralize a small part of the fluid with which they are washed down and the forcing of fruit drinks increases the acidity of the urine.

It is therefore apparent that if renal complications are to be avoided when giving sulphonamides, all fruit drinks must be strictly forbidden, and the extra fluids required must be given as water, milk, tea etc.—I am, etc.,

London E 7

PETRONELLA POTTER

Shortage of Nurses

SIR—My father died recently after a long illness. Towards the end I engaged a man to help with the night-nursing. He was an excellent fellow and a most competent nurse. He made a living doing casual private nursing as he was not qualified to obtain the responsible hospital post he desired. Twelve years he had spent in the R.A.M.C., and although he had left the Service with an excellent character and the qualification of First Class Nursing Orderly he had sought in vain for a civilian nursing post suitable for a man of his ability. He was only 30, keen, competent, and reliable—but he had no civilian qualifications. Training for State Registration was out of the question, he was a family man and had to live. He could call himself a Service Trained Male Nurse, but this would open to him only the menial and less responsible positions in nursing.

This must happen so often, Sir, that I wonder how the Service medical authorities can be blind to its effects. Time and time again good ex-Service male nurses drift into other occupations because they are unqualified by civilian standards. This loss to nursing is all the more tragic at the present time when public assistance hospitals are closed for want of trained staff. My experience has convinced me that a scheme could be evolved whereby orderlies in all three Services would be obliged to obtain a nursing diploma as a prerequisite to advancement. The professional examinations for higher rank or rating could and should be brought into line with civilian standards. In this way the qualified Service nurse would automatically be a qualified civilian nurse and could be fully and usefully employed on his discharge from the Service.

I know it will be argued that while in the Service these men have the chance of taking civilian examinations if they wish. I doubt if this is always true, but in any case the initiative should be with the authorities. If this waste of nursing personnel is to be checked, orderlies must be made to take examinations recognized for a nursing diploma—and the fees must be paid by the State—I am, etc.,

London NW 1

R. HOWELL ROBERTS

SIR—Would it not be helpful if there could be a scheme whereby nurses could attend patients during early convalescence in their own homes, thus allowing more room in hospitals for acute cases and for helping to reduce the present long waiting-lists? If recruitment to the nursing profession were to be carried out according to grades there should be a supply to meet such a demand—say Grade A, where the standard of entry was dependent more on character and personality than on the "knack" of having passed examinations. Such nurses would be able to carry out all the duties required of a good practical nurse without having to pass examinations, which proves so great a stumbling block to the recruitment of nurses at present.

This Grade A nurse would probably include most of those who are lost to the profession at present on account of the amount of theoretical lectures and reading they have to do for even the Preliminary Nursing Examination. They should get a thoroughly practical training and could qualify for an external nursing service attached to their training school or interchange with other hospitals. Under such a scheme nurses could be sent home with early convalescent patients or they could be sent out to attend other patients in their homes at charges drawn up according to scale by the hospital almoner. A system of home nurses should help to reduce the number of patients who have to go to hospital for observation or for only a few days' treatment or because they live alone or have nobody to attend them at home. The external auxiliary nurses should be able to live at the hospital and be called in to help there when necessary for, say, only a limited number of weeks each year. There should be a block of one- or two-room flatlets with service, catering, and laundry facilities. They should be relieved of certain household responsibilities and so get proper leisure. At present private nurses often live in one room or move about from room to room in a club between cases. They should be able to rent the flatlet and come back to their own room and not have to pack up before going to a case. Only so long as they served the hospital should they be allowed to be tenants of a flat, but they should be tenants on the same terms as tenants of any other block of flats in the country.

Grade B nurses would be mostly women who wish to enter the profession when they are older and have gained some experience of the world and people. The age limit of 28 years would not be too high for such entrants. Grade B nurses would most likely be qualified to shoulder the responsibility of sisters, house sisters,

sister tutors, or matrons. If any Grade A nurse proved to be exceptionally able she should be allowed to transfer to Grade B at the end of her first year and have an extended period of training of, say, six months along with the examinations required for Grade B nurses.

Grade O nursing orderlies are those women who like looking after and doing things for other people but who from educational and other reasons cannot take up nursing proper. They could carry out routine duties in the wards, in the kitchen, and in the residential quarters. They should be moved about during their training but later become attached to one special ward or sister when such an arrangement is proved mutually agreeable. They would then take an interest in their ward. They should be allowed to live in or live out.

Why not make nursing a compulsory national service and make the period of it, eighteen months or one year, sufficiently attractive to make the maidens want to continue training or at least look forward to the sixty days' service later as "supplies" for holiday relief of the regular nursing staff? These are just a few points which I think could be further considered by those responsible for the recruitment of nurses—I am, etc.,

WINNIFRED M. GRAY

Admissions to Hospitals

SIR—One hopes that a recent experience does not reveal the shape of things to come.

In an endeavour to get a patient with pneumonia into hospital (there being no one at home capable of nursing him) I phoned a local authority hospital—his area hospital—and was informed that they now received mental cases only. That is hospital A. I phoned hospital B, on the recommendation of A, and was told that they could not accept the case, as they were not receiving that day. I phoned hospital C, on the recommendation of B, and was told that it was not likely that they could accept and that all they could do would be to put the case on the waiting list, but that they would phone me back. In about an hour C phoned to say that hospital B, which had refused me would take the case. To my protests at the delay and lack of liaison I was told that this was constantly happening since the grouping of hospitals had taken place. This I believe is correct, for in more than 20 years of practice in the same area I cannot recollect having spent one quarter of the time in getting a patient admitted, nor can I recollect having heard the suggestion made that an acute case as this should be put on the waiting list.

In view of the negotiations in progress one feels that this sort of thing should be seriously considered now, and the pros and cons of grouping accurately assessed before the whole hospital system of the country is committed to such a plan—I am, etc.,

W. LEES TEMPLETON

Surgical Anatomy of the Vagina

SIR,—Students of gynaecology will be extremely grateful to Mr. Wilfred Shaw (April 12, p. 477) for having described the surgical anatomy and operations of the vagina in his characteristic lucid and masterly style. The terminology suggested for the various grooves and sulci cannot be improved upon except in the case of the "transverse vaginal sulcus," which I think, deserves the nomenclature of "urethro-vesical sulcus" as being more definite, descriptive, and going well with the term "bladder sulcus" of Mr. Shaw. The terms "transverse" and "vaginal" are both quite superfluous because all the grooves described by Mr. Shaw, except the obvious "oblique vaginal folds," are transverse, and they are all situated on the anterior vaginal wall.

In the description of vaginal hysterectomy for severe degrees of uterine prolapse I feel that the name of A. C. Palmer has been inadvertently omitted. The technique independently devised by A. C. Palmer and described by him in the *British Medical Journal* 1934, 2, 899, and in the *Proc. Roy. Soc. Med.* 1937, 30, 1353, though similar to that of Mayo and Franz is not quite identical with it and lays emphasis on certain features which merited at least a passing mention of his name, especially when Mr. Shaw himself, in his *Textbook of Gynaecology* (1941), has associated Palmer's name with Mayo in the description of the operation—I am, etc.,

London WC 1

B. S. SURTT

Vitamin B₁ and Painless Childbirth

SIR,—My attention was recently directed to an article in the *Soviet News* (Jan 10, 1947) entitled *Painless Childbirth—a Promising Soviet Experiment*. The following extracts present the main points.

It has been observed that the urine of women in childbirth even in cases where the ordinary diet includes a sufficiency of vitamins contains an exceptionally small quantity of vitamin B₁. This suggests that the body's demand for this vitamin is stepped up during the childbearing process."

To determine whether deficiency of vitamin B₁ had any relationship to the pain experienced during childbirth the Central Institute of Obstetrics and Gynaecology of the U.S.S.R. carried out an investigation in Leningrad in 1945 and over 900 painless births were achieved. Different routes of administration were tried.

At present the usual procedure is to begin with an intramuscular injection of 60 mg., followed, if the pains recur, either by another smaller injection or by doses through the mouth at an interval of half an hour. Relief from pain was felt within 10 to 15 minutes of the first injection. In nearly half the test cases, 40%, the pains were relieved during the whole process of birth. In 51.2% of the cases there was a prolonged alleviation of pain. In 3.2% of the cases the effect was of short duration. Only in 5.6% was no relief experienced. The expectation that vitamin B₁ would not only relieve pain, but speed up the process of delivery, was based on such facts as that a deficiency of vitamin B₁ in the organism of a woman in childbirth was known to lead to a decrease in the formation of glycogen, resulting in the exhaustion of the muscular tissues. The introduction of the vitamin, therefore by facilitating the accumulation of glycogen in the muscular tissue, would create a reserve of energy of extreme importance in parturition, which demands a big expenditure of muscular energy often over a considerable period of time. The introduction of the vitamin does in fact speed up the process of delivery to a very marked extent: the average time is halved."

Confronted by these facts I decided to put them to the test. Ten consecutive patients admitted to the maternity ward were given vitamin B₁ during the first stage of labour. The dosage adopted was 50 mg. of the vitamin by intramuscular injection followed by 3 mg. orally at half-hourly intervals. There was no marked alleviation of pain in the first seven cases so the dosage was increased to 100 mg. intramuscularly in the remaining three.

Four of the patients said the injections had no effect on the pains, four were relieved for a short period (approximately one hour) and two stated that the pains became more severe after the injections. The increased dosage did not appear to have any different effect on the pains. There was an apparent decrease in the duration of labour after the vitamin was given in all cases but this was impossible to assess accurately without controls. All the babies were born normally and were unaffected by the treatment.

This series of cases is too small to yield statistically significant results and no definite conclusions can be drawn. It was intended as a preliminary experiment before proceeding to a full scale investigation with a controlled group of patients. Unfortunately I am unable to carry out this investigation, but would suggest, in view of the importance of analgesia in labour, that some other investigator continue this research in order to confirm or disprove the Soviet claims—I am, etc.

London S W 20

D M ZAUSMER

Pethidine in Labour

SIR—In her comprehensive article on pethidine in labour (April 5, p. 437) Miss Josephine Barnes touches on the effect of pethidine on the duration of labour. She suggests that to assess this accurately a controlled experiment is necessary, the drug being given to alternate primigravidae in labour.

While I was working in the Nuffield Department of Obstetrics and Gynaecology at Oxford I undertook such an experiment with the help of Mr C. Scott Russell who was responsible for the statistical analyses. The patients selected were primigravidae of 38 or more weeks of pregnancy in the first stage of labour, and they were allotted to a pethidine group and a control group in rotation. On admission the descent of the head and the dilatation of the os were determined. The first

group were given pethidine 100 mg. at once by intramuscular injection. This was repeated every four hours so long as sedation was required. No other sedative was used though gas and air analgesia was allowed. The second group were given a mixture of tincture of opium and chloral morphine, or heroin and hebaral ' according to requirements. They, also, were allowed gas and air analgesia.

When there were 13 patients in each group a pilot survey was carried out to see whether the experiment was likely to yield any useful information. The total duration of first and second stages was estimated and the average for each group was calculated. The average of the pethidine cases was 20 hours as against 26 hours for the control group. An analysis of variance, however, showed that the variation within the groups was so great that the difference between the groups was nowhere near significance level.

The experiment was therefore continued in a modified form. The total duration of first and second stages obviously was not a good estimate of the effect of the drug so in subsequent cases the time from the onset of treatment till the delivery of the baby was recorded. It was thought that useful information might be obtained by analysing the cases in such a way as to compare more accurately like with like.

Each group was subdivided into four categories according to the descent of the head on admission—high engaged, mid cavity and deep. In each category cases were tabulated according to dilatation of the os (0-5 fingers) and age (under 25, 25-35, over 35). It was then fairly easy to select pairs, one from each group, that could reasonably be compared with each other. In selecting each pair I made certain that the weights of the babies were alike and also the mode of delivery—for example a patient who had had a spontaneous birth was not compared with one who was delivered by forceps. By this means of selection 21 comparable pairs were available for study. They showed that from the time of commencement of treatment the labour of those patients having pethidine was shorter than in controls 10 times, longer than in controls 10 times, and exactly the same once. In fact, it was obvious from superficial inspection that there was no material difference in the two groups.

This experiment, then, did not justify any conclusion as to the effect of pethidine on the duration of labour. I record it only in order that others attempting to elucidate the point may design their experiments in such a way as to reach a more helpful conclusion—I am, etc.,

London E 1

ELIZABETH M ROSE

A Spinal Injury Centre

SIR—As a recent importation into a mining area I hesitate in the face of greater experience, but I would appreciate the opinion of other general practitioners in such areas on the question of spinal injuries in the mines. I gather that such injuries are not uncommon as a result of rock and coal falls and usually take the form of compression fractures or spinal contusion. After such injuries, with laminectomy, etc. duly performed when indicated, the patient returns, only too commonly to his own home an object of pity, invalid or semi-invalid, to exist on a pittance of compensation aided by public assistance. Eventually ascending urinary infection or ascending degeneration of the cord concludes his story, but this may be many years later.

I would suggest that there is a strong case for a spinal injury centre, on the lines of the Head Injury Centre at St. Hugh's where such cases could be transferred as soon as they are fit to travel from the local hospitals. Here due attention could be given to mental as well as physical rehabilitation, the man could have the benefit of the best consultant opinion, orthopaedic and neurosurgical, and there would be no problem of shortage of accommodation. The project could deal with all industrial spinal injuries of major character, or, if the Coal Board should consider the problem as important as the provision of hair cream in pit-head baths, perhaps they would like to sponsor the idea for the injured miner—I am, etc.,

Kinsley near Pontefract

K V JACKSON

* An account of the miners' rehabilitation centre at Berrill Hill Hall was given by E. A. Nicoll in an article entitled 'Rehabilitation of the Injured' in the *Journal* of April 5, 1941 (p. 501)—Ed. B.M.J.

POINTS FROM LETTERS

The NHS Act

Dr R H P HICK (Bracknell, Berks.) writes It seems to me that the general trend of the policy of the B.M.A. is a gradual veering round to acceptance of the Bevan Act. You will be doing a great disservice to your members if you do not fight it tooth and nail and encourage every member to back you up.

"Free Health Service"

Dr LESLIE HARTLEY (Camberley, Surrey) writes The public will not mind paying an extra shilling for their packet of cigarettes, as Dr Dalton told them in his budget speech that it was to pay for the free Health Service. When the new Service comes into force on All Fools Day next year, just before the budget, the jovial doctor will no doubt put a shilling on the pint also in Freedom's name.

"Rock a bye Baby"

Dr A P DERHAM (Victoria, Australia) writes I must with thousands of others congratulate you on producing the "blizzard" numbers of which I have received Nos 4494 and 4495. In the latter there is an answer to a question which calls for comment.

Q—Is it harmful to rock a child to sleep? A—No. No answer could be more brief or dogmatic. A better answer would have been "Yes and No." The choice would rest on the question.

What kind of person do you wish the child to be? For brevity I shall be as dogmatic as your "No" authority. A child is rocked to sleep because otherwise it cries or stays awake. A child may cry or stay awake for a variety of reasons: flea, safety pin, wind, wet napkin, overstimulation, etc. Many of these can be diagnosed over the telephone—the most convenient way until we get television. After the first few occasions, however, a child usually cries because he finds that by so doing he can establish a certain power over his parents. He is fulfilling one of his fundamental instincts. If he is rocked to sleep he may become an Alexander, a Napoleon, or even a Winston Churchill, but he is more likely to become a querulous person, hated as his age increases by his nephews and his nieces. If he is allowed to cry it out he may become a Shackleton, an Oates, or a Scott, but he will at least have learnt to make his first adjustment to life the hard way and will have gained a victory over himself instead of over his parents. A young mother once took her baby to a famous French paediatricist. She asked,

Doctor, when should I begin to train my baby? He asked, How old is your baby? She replied, Six weeks old. He replied, 'Madam, you are six weeks too late.' Q—Do I really believe all this? A—Yes and No.

Electric Convulsion Therapy

Dr P L BACKUS (London, NW 1) writes Dr S M Witteridge (April 12, p. 505) gives the necessary emphasis to proper procedure in electroplexy, and it is most timely and important. As a gag I have adopted the use of two or three pieces of heavy stethoscope tubing about 2½ in. (6.3 cm.) long bound together and covered lightly with sterile gauze when in use. This allows a free airway for the passage of the oxygen into the posterior fauces. It has been my custom to use 5% carbon dioxide with pure oxygen, and the administration of the same is continued until the patient rouses sufficiently to reject the mask, or for at least three minutes.

Changing Medicine

Capt D M SINCLAIR R.A.M.C., writes The following little historical note might give one food for thought. While glancing through the sixth (1905-6) edition of Osler's *Principles and Practice of Medicine* I came across this paragraph in relation to diabetes mellitus: glycosuria occurs. This may theoretically be produced by functional or organic disease of the islands of Langerhans in the pancreas. These islands of cells probably produce a glycolytic ferment or body. "The owner of the book, apparently rather progressive in outlook, has crossed out the above paragraph and inserted a marginal note: "There are no islands of Langerhans. They are merely alveolar changes in the pancreas." *Vide BMJ* Sept. 29, 1906, Stirling's article.

* The marginal note refers to an unsigned book review on *Recent Advances in the Physiology of Digestion* by Prof. E. H. Stirling which appeared in the *Journal* (Sept. 29, 1906, p. 781) and in which the following statement occurs: "The islets of Langerhans, of which we have heard so much recently, as the parts of the pancreas especially related to the production of the internal secretion concerned in the assimilation of glucose, and whose destruction has been said to be the cause of diabetes, turn out to be merely stages in the growth of pancreatic alveoli, all parts of the gland reverting to this condition as the result of activity so that there is a constant formation and disappearance of these islets: the relation of the pancreas to diabetes remains an unsolved problem."—*Ed. BMJ*

Obituary

SIR ALMROTH WRIGHT, KBE, CB,
MD, LL.D., FR.S., F.R.C.P.

Sir Almroth Wright died at his home in Pembroke Square, London, on April 30. He was in his 86th year.

A son of the Rev. Charles H. H. Wright, D.D., Almroth Edward Wright was born in 1861. His mother was the daughter of Nils W. Almroth, governor of the Swedish Royal Mint. Almroth Wright received his early education at Dublin University, where he took the B.A. and was awarded a gold medal in

Photograph of Sir Almroth Wright taken in 1940

modern literature. He qualified M.B., B.Ch. in 1883 and, being awarded a medical travelling prize, was enabled to take up a studentship at the Inns of Court in jurisprudence and Roman and international law. Later he studied at the universities of Leipzig, Strasbourg, and Marburg before becoming a demonstrator of pathology at Cambridge University in 1887. While at Cambridge he was granted a Grocers Company research scholarship. Two years later he went on to take the M.D. of Dublin, and accepted soon afterwards the position of demonstrator in physiology at Sydney University. Only three years later, at the age of 31, he became professor of pathology at the Army Medical School, Netley. At this time he had already done important work in devising a coagulometer for estimating the coagulation time of the blood and in indicating for the first time the part played by calcium salts in the coagulation of the blood. His tenure of this chair lasted for ten years, for two of which he was also a member of the Indian Plague Commission. It was in the early part of this century that he became pathologist to St. Mary's Hospital. In 1908 with the aid of Lord Balfour, Lord Ivergh, Lord Justice Fletcher Moulton and others, Wright founded the Inoculation Department of St. Mary's Hospital as a separate financial entity; he remained director of this until last year. The Inoculation Department rented from the hospital certain unused wards; these were fitted out as laboratories and so used

in 1934 when the generous contributions by Lord Iveagh and others enabled the present laboratories to be built adjoining the new Medical School. He was a founder member of the Medical Research Club.

Wright's pioneer work on immunization began in 1896, when, following the inspiration of Haffkine's inoculation of cases of cholera and Pfeiffer's inoculation of two cases of typhoid he introduced the idea of immunization by means of vaccines made of killed bacteria (*Lancet* Sept 19, 1896). On the Association of Serous Haemorrhages with Conditions of Defective Blood-coagulability. In a series of papers on antityphoid inoculation he published one jointly with W. B. Leishman in the *British Medical Journal* of Jan 20, 1900 under the title of 'Remarks on the Results Which Have Been Obtained by the Antityphoid Inoculations'. With S. R. Douglas he gave an account (*Proc Roy Soc Lond* 1903, 72, 357) in 1903 of experiments which showed the presence in the serum of substances (named by him opsonins) which, as Bulloch puts it, 'in some way alter the microbe so that it falls an easy prey to the leucocytes'. From this work Wright developed his 'opsonic index'.

In 1904 Wright published his *Short Treatise on Antityphoid Inoculation Containing an Exposition of the Principles of the Method and a Summary of the Results Achieved by its Application*—the first and perhaps the most important of the books he wrote. It was soon translated into French and German, and editions appeared in many other countries. His *Principles of Microscopy* appeared in 1906, and *Studies on Immunization and Their Application to the Diagnosis and Treatment of Bacterial Infections* was printed in this country and in Germany in 1909. Other books that bore his name marked different phases of his life and varying aspects of his many activities. In collaboration with Leonard Colebrook there was produced in 1912 a handbook for the medical research laboratory and the research ward, *Technique of the Teat and Capillary Glass Tube*—in its own way a classic. This was followed in 1914 by *Pharmaco-Therapy and Preventive Inoculation applied to Pneumonia in the African Native*. A product of his war experience published in 1915 was *Wound Infections and Some New Methods for the Study of the Various Factors which come into Consideration in their Treatment*. His work during the war of 1914-18 on the saline treatment of wounds ended in the Carrel-Dakin-method. He contributed numerous papers to scientific journals throughout the world. In his *The Unexpurgated Case against Woman's Suffrage* he illustrated his anti-feminist outlook. Another example of his polemical ability was his rejoinder to Sir Watson Cheyne's advocacy of antiseptic procedures. Wright concluded by writing this: "I would invite them to the study of the psychology of obsession, and would have as many as follow the intellectually glorious calling of medicine hearken to that saying of Emerson 'God has given to every mind a choice between truth and repose'."

It was in the years 1914-18 that it became clear that Almroth Wright and his colleagues had altered the course of history. Enteric fever had taken a tragic toll in the South African War. Twenty years later had treatment been the same, it is estimated that over 125,000 men in the British Forces alone would have died. Actually deaths from this cause during the whole of the war numbered only 1191. Almroth Wright, who at the outbreak of war was principal of the Institute of Pathology and Research at St. Mary's Hospital and professor of experimental pathology at the University of London, served as a consultant physician in France, while at home, in the first two years of the war, the department he had created at St. Mary's Hospital provided sufficient antityphoid vaccine for the immunization of four and a half million persons—a figure which may be compared with his first large-scale inoculation of over three thousand soldiers in India, two years after he had arrived at his first definite conclusions on the subject of typhoid immunization on the basis of experiments worked out at Netley in the years 1896-7. From this work of Wright's vaccine therapy may be said to have originated. He believed that vaccine therapy had a future in the treatment of established infection and spent much time between 1901 and 1914 in pursuing this idea. During his last years Almroth Wright was engaged in publishing his scientific papers in a series of volumes and in completing his philosophical work on logic and belief.

In 1906 a knighthood was conferred on him, and he was made a Fellow of the Royal Society. Two years later, in 1908, he was awarded the Fothergillian medal of the Medical Society of London. At the International Congress of Medicine in London in 1913 he was awarded the Hungarian prize. He was created a Knight of the British Empire in 1918, having been made a C.B. in 1915. He valued perhaps most, however, the honour which was done him by the Royal Society of Medicine when he became its first gold medallist. It was through the gift of an anonymous Fellow of the Royal Society of Medicine that the Society was able to give a triennial gold medal open to medical practitioners throughout the world, and the donor expressed the hope that the first award would be made with special regard to medical services during the war. On Nov 11, 1920 the President of the Society Sir John Bland Sutton, presented the medal for the first time to Sir Almroth Wright, whose address on this occasion was a general one on the conditions of medical research, in the course of which he pleaded for the institution of research work in hospitals by a staff not of clinical men but of men with clinical knowledge trained in methods of discovering immediate effects.

During and after the war the value of the work he had done for the allied Forces was recognized by the conferment of honours by France, by Belgium, and by Serbia. He was elected an honorary member of the Société Médicale des Hôpitaux de Paris in 1919, and the honorary M.D. of Paris was conferred upon him in 1924. He was an Associate Member of the Académie de Médecine de Paris, and a corresponding member of the Institute of France. He was made an Honorary Fellow of the Royal College of Physicians of Ireland and of the Royal College of Surgeons of Ireland. Dublin made him an honorary D.Sc. and an honorary Fellow of Trinity College. Belfast conferred its LL.D. upon him and made him an honorary Burgess of the City, and the University of Leeds made him an honorary D.Sc. At the Annual Meeting of the British Medical Association in Belfast in 1909 he was president of the Section of Haematology and Vaccine Therapy. Then again at the Centenary Meeting in London in 1932 he was president of the Section of Bacteriology. He had a further point of contact with the Association in 1927, when, in connexion with the Annual Meeting, the University of Edinburgh held a special graduation ceremonial and conferred upon him the honorary degree of Doctor of Laws.

It was on his seventy-fifth birthday that tribute was paid to him by his colleagues, when in the laboratory of the inoculation department of St. Mary's Hospital in March, 1936, Sir Henry Dale unveiled a portrait bust of him, the work of Mr. Donald Gilbert, and presented it, together with a small volume containing an engrossed address and the names of about 250 colleagues who had participated in the testimonial. Paul Ehrlich, Sir Henry Dale observed at the presentation ceremony, once said that he could carry out all the researches he wanted if he were given a supply of dyes and other chemicals, a handful of test tubes, a water-tap, and a bunch of blotting paper. Almroth Wright, Sir Henry continued, was no more exigent in his requirements. A microscope, an incubator, some glass tubing, a few rubber teats, a little plasticine, and some vaseline were all that he needed in the way of apparatus. The material for his research was a few drops of human blood, which he obtained from himself, his friends, or his patients. "I sometimes think," Sir Henry added, "we should regard Sir Almroth Wright as one of the burglars of Nature's mysteries, fashioning the skeleton keys with his own skilful hands from the most homely material, and then using them, with the touch of genius, to force the intricate locks."

Almroth Wright said the praise he valued was the praise of his compeers, and he quoted what Metchnikoff had said of him. He is the sort of man who has very good original thoughts—but he has also many thoughts which are only original. And he concluded his acknowledgment of the presentation with a quotation from Bunyan—from Mr. Valiant-for-Truth who stood at the brink of the river of death looking back over the labour and toil of his life: "I leave my sword to him that shall succeed me in my pilgrimage, and my courage and skill to him that can get it."

[Press Portrait Bureau]

Mr G Bernard Shaw writes In the obituary notices, and specially in the broadcast too much has been made of Wright's early experiments in immunization and too little of his later work.

In my opinion one of his most illuminating and pregnant utterances was the single sentence he interjected at a lecture delivered by me at his invitation in St Mary's Hospital I was calling attention to the reckless crediting to bacterial inoculation of results though all the available controls pointed to sanitation as the real cause Wright's comment on the spur of the moment was "I believe the effect of sanitation is aesthetic"

Little has been said of his treatment of wounds in the 1914-18 war by salines, his advocacy of which involved a contemptuous belabouring of Jenner and Lister as scientific immunizers, and his explicit statement that his study of salines was a reduction to scientific essentials of the rude poultices of soap and sugar used by old wives in Irish villages

Nothing has been said of his efforts to excogitate a scientific method of reasoning, and his invention of new and necessary words To these he attached great importance, knowing that our scientific authorities are strong in facts but weak in logic

The net effect of the obituaries is to underrate Wright even more than he underrated himself

Sir Henry Dale writes It is early yet to attempt a prediction as to the permanence of many individual items of Almroth Wright's large and varied output during his very long career of research He himself showed in his later years what might have seemed at least at first sight, a curious inconsistency of attitude with regard to his own scientific publications He had on the one hand, arranged for the republication of all of them in collected form, believing doubtless that, even where their results had been overtaken by advances made from different angles, they had in their own way and time contributed significantly to the progress of knowledge On the other hand, with his ingenuous curiosity undimmed by age, and a mind still remarkably open to the interest of novelty, he seemed to be eagerly searching for and finding evidence which called for revision of some of his earlier ideas, and preparing to jettison them with something like gusto Wright was a man whose methods of work and ways of thinking together with his attractive and stimulating personality evoked a rare intensity of devotion and enthusiasm in his co-workers, on the other hand, his findings and his presentation of them were apt to excite opposition and dispute—partly, no doubt, because he himself so enjoyed the clash of opinion and the cut and thrust of argument with a well grounded confidence in his own prowess His interests and activities ranged widely over the years, the one unifying character in all his researches being, perhaps their concern with the blood and its constituents, and their various functions and properties—coagulation in his earliest years of research, and, for most of his life the different factors and manifestations of immunity and the ways of modifying them Probably the future will give highest rank, among his contributions to pathology and practical medicine, to his development of active immunization and his vigorous advocacy of its applications at a time when the possibilities of passive immunization with sera was attracting so predominant a share of the general interest His immunization against the enteric bacilli with killed cultures was the first and immensely important outcome some of the later attempts at similar immunization, with heat-killed cultures of other pathogens have had less success, but the principle of supplementing passive by active methods of immunization is still growing in importance, and Wright was the most influential and consistent of its pioneers and early advocates

Those of us who knew Wright well and had the great privilege of his friendship will retain, as the dominant impression of him, the picture of his figure seated all day and far into the night at his laboratory bench, working with tireless interest and always with his own hands and eyes He used the simplest appliances—glass tubing a gas burner, a dab of plasticine a handful of rubber teats—but like his friend Paul Ehrlich Wright made himself a veritable virtuoso of the limited gamut of his chosen instrument He had an artist's, a fine craftsman's joy in his work and he left it only at the compulsion of physical need He still held up that example of devoted and

intensely personal research at an age long past that at which most men feel the need of relaxation and rest One has the feeling that something like an epoch in research comes to an end with his death

Dr John Freeman writes Soon after the Boer War Dr Almroth Wright came to St Mary's Hospital as pathologist he had just resigned from his Army professorship as part of the fight to get adopted his prophylactic inoculation against typhoid Lord Haldane's insistence on a knighthood which Wright genuinely regretted, was another part of the same plan

Wright soon made his presence felt at St Mary's His personality seemed like a draught of wine to the young men of that day his freedom of thought, freedom of manner, and freedom of language, while distasteful to the more orthodox elders, was a heady but stimulating brew for us youngsters His mind seemed free from conventional assumptions He was always ready to consider any proposition however unlikely and by whomsoever presented so long as it was put forward honestly and was backed logically He hated any suggestion of pomposity Dignity is a mysterious gesture of the body designed to hide deficiencies of the mind," he quoted "Except ye become as little children ye shall not enter into the Kingdom of Science," he misquoted to anyone trying to bludgeon him with authority If he thought it necessary he could be ruthless, he had not gone to Trinity, Dublin for nothing and he loved a good fight "Unless the physicians soon learn to do something, they will be reduced to a position little better than that of the head nurse," he declaimed at his first public lecture at St Mary's, and two physicians walked out in a huff

Though he had a short and rough way with the pompous he was always gentle with hospital patients and with all who were trying to work Countless stories could be told illustrating this here is one We were all sitting looking down our microscopes when a fashionably dressed doctor quite unknown to any of us walked in holding his glossy top hat in one hand and his gloves and malacca cane in the other He announced with satisfaction that he had just been appointed Physician in Ordinary to one of the Crowned Heads of Europe and he would like to know if we had any hints of new treatment that could help him Wright looked up from his microscope, said reflectively, "No, I don't think so," and went on with his work again While the resplendent dandy was still standing nonplussed in the centre of the laboratory, a navvy in hobnail boots and corduroy trousers, nervously twisting his cap in his hand, came in and said in a husky voice "I didn't ought be rights to come in here Guvner, but could one of you gentlemen—?" Wright at once bounded to his feet, saying, "What may I have the pleasure of doing for you my friend?"

Wright soon began seeing out-patients in his laboratory their numbers mounted to a flood which blocked stairways and passages Later he bargained for hospital beds to be under our control for special investigations—the "Almroth Wright Wards" as they are now called It was necessary to keep on seeing patients because we all needed the 'pain in the mind' which came when looking impotently at a little understood case, he insisted that we all needed that galling spur to complacency

Forty years ago he asked that we should put on his tombstone a quotation from Emerson's essay on intellect 'God offers to every mind its choice between truth and repose' And he used to add, peering at you over his spectacles and with his eyebrows twitching, "Repose is the more fashionable" He constantly reiterated that we needed this "pain in the mind", it was what drove him to furious work In his strength he would work in his laboratory regularly until 3 a.m., and often this stretched until 5 or 7 a.m. and he was generally one of the last to leave

He was curiously ascetic in his habits "Art is a whore with whom I played in my youth," he said A good dinner he denounced as a "voluptuary pleasure," and I once made him really angry by pressing on him a glass of benedictine—which I knew he loved On the other hand, he took enormous pains to get exactly the colours he wanted in his beloved flower garden at Stoke Poges, for him that was not a voluptuary pleasure He was chary of listening to music because it affected him too much, and made him 'give at the joints'

Yet he could hardly have enough of poetry, and Dante and Milton were his poets during tedious motor journeys in the first great war he would quote Milton to himself from memory—his mouth silently muttering for an hour at a time. I only once got him to go to a theatre the play was *Man and Superman* by his friend Bernard Shaw. Later, of course, Shaw put him into *The Doctor's Dilemma*. Everyone recognized him as the scientific Ridgeon, but I have always thought he was as much like the Irish Sir Patrick Cullen, and that Shaw had split Wright into the two characters—one ruthless and the other so very lovable.

If Art was a whore Philosophy was a beloved mistress from whom he never wished to break free, though Lord Balfour used to beg him to give her up. When I first went to live in his house, forty five years ago, I found a much corrected galley proof headed "The Physiology of Belief", that name has changed many times since, but he was still working at it up to the last days of his life. Almost his last conscious act was to read a recently written bit to his own son.

Dr ALEXANDER ASHER, of Findhorn, Morayshire, died on April 15 at the age of 82. Dr Asher was the son of an Inverness merchant. He was educated at Inverness Academy and Edinburgh University, obtaining his medical qualification there in 1888. He spent his professional life in Thurso, where he built up a large practice. A man of great integrity, he earned the confidence and trust of his patients and was highly respected by all who knew him. In manner he was quiet and unassuming, and one had to know him well to appreciate fully his many excellent qualities. He became a member of the British Medical Association in 1899, and in the work of the Association he found his main hobby. He was honorary secretary of the Caithness and Sutherland Division from 1915 to 1934, and it was in large measure due to his devoted efforts that the work of the Division in a scattered and difficult area was carried on so efficiently. He also acted as president of the Northern Counties of Scotland Branch, and for four years was a member of the Scottish Committee. His activities were not confined, however, to medical matters. His sterling qualities were recognized in his election for a term as provost of Thurso. He was a justice of the peace for the County of Caithness, and was also elected a member of the county education authority. In his later years he was much troubled by failing eyesight and he retired several years ago to the village of Findhorn. He leaves behind him a record of faithful and conscientious service to his fellow doctors and to the community as a whole.

Dr JOHN MORLAND SMITH died on April 16 at the early age of 32. Dr Morland Smith was a student of Middlesex Hospital. He took the Cambridge M.A. and the Conjoint Diploma in 1940, and the D.A. a year later. For a short time he was junior resident anaesthetist at the Middlesex before being appointed senior anaesthetist at the Ministry of Pensions Hospital at Stoke Mandeville. His home was in Bournemouth.

A colleague writes: In the untimely death of Dr Morland Smith the Plastic Surgery Department of the Stoke Mandeville Hospital (Ministry of Pensions) Aylesbury, has sustained a loss from which it will be difficult indeed to recover. He was the most important and indispensable individual member of the team which has worked hard and harmoniously there throughout the difficult war years. "Johnnie" as his likable personality made him known to us all, had a real flair for his specialty, and those of us who watched his progress with fatherly interest predicted for him a position of high eminence among this country's anaesthetists in the spheres of both practice and research. To observe the care and gentleness which he expended on the intubation of infant patients requiring operations for the repair of congenital defects of lip and palate was to realize that here was a true artist at work. Never content with anything merely "good enough" he became a real adept at providing that light degree of anaesthesia which, whilst ample for the surgeon to carry out even lengthy operations without embarrassment left him with a child exhibiting active reflexes when the work was finished. In this way he robbed our work on infants of all anxiety. He was one of those anaesthetists who always saw his patients on the day before operation and followed their progress after operation in his desire to discover faults and devise improvements. He kept careful records of the many hundreds of patients he anaesthetized and it is a tragedy indeed that these may never now be analysed. "Johnnie" was on the eve of marriage and of military service and our sympathy for his mother and fiancée is deep and sincere.

Medico-Legal

MENINGITIS FOLLOWING SPINAL ANAESTHESIA

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Mr G. G. Voller, of Southsea, fractured the shaft of his right femur when playing football in April, 1944. He was then aged just over 18. He was taken to St Mary's Hospital, Portsmouth, which is maintained by the corporation as a public hospital. After three weeks the fracture had failed to unite and an operation was performed. Earlier injections of "evipan" had not given enough relaxation, and so a spinal injection of "nupercaine" was given. The operation was taking place, for convenience, in the ward, but the syringe and needles came from the operating theatre. Shortly afterwards the patient developed meningitis, which left him with permanent paralysis of both legs and incontinence of urine. Suing through his father, he claimed damages against the corporation, Dr R. J. Hamer Hodges, a resident medical officer, Mr A. Gordon Ord, the consultant orthopaedic surgeon who performed the operation, and Dr S. F. Hans, the senior resident medical officer, who acted as anaesthetist.

All the defendants denied negligence. The corporation denied liability for the acts of the medical practitioners, and Dr Hans pleaded that since the action against him was not started within twelve months from the injury he was protected by the Public Authorities Protection Act, 1934, and the Limitation Act, 1939. Mr Voller also pleaded that no consent to the giving of the anaesthetic had been obtained, but this point was not pursued. The case turned on the propriety of the technique of sterilizing the syringe and the Howard Jones needle.

Mrs V. F. Spacey, formerly a nursing sister, giving evidence for the defence, said that immediately after use a syringe was rinsed with water soaked in pure lysol and then in methylated spirits, and finally placed in a glass container with formalin tablets. So far as she knew, the normal procedure was followed in the present case.

Mr E. Hume Kendall, a consulting surgeon, said that he considered these steps inadequate. Complete protection could be given only by sterilization by superheated steam in an autoclave. He agreed that the risk was small, but recalled reports of a number of cases in the medical journals. The method described was similar to that in general use at the time, but since this accident he himself had given instructions for sterilization by autoclave. He thought that infection could not be introduced into the spinal canal without a breach of technique.

Dr R. C. Macpherson, formerly medical superintendent at St Mary's, said that the hospital had used an autoclave since 1917 but that none of the syringes in use in 1944 would have stood up to the heat. Up to 1946, when he had retired, the autoclave was still not used there for sterilizing syringes.

Dr R. W. Cope, a consultant anaesthetist, said he was satisfied that Dr Hans had administered the anaesthetic in accordance with the approved practice. In a number of similar cases search had been made for breaches of technique but none could be found. He quoted an authority who reported only two cases of meningitis in more than 14,000 injections. He thought airborne infection the most likely source in this case and could not see any fault in the aseptic technique of the hospital.¹

Judgment

Mr Justice Birkett, giving his reserved judgment,² said that he found no evidence against any of the defendants in the treatment of the fractured femur, in the decision to give a spinal anaesthetic, in the treatment of the patient after meningitis had been diagnosed, or in the giving of the injection in the ward instead of the theatre. He found that the meningitis was the direct result of the spinal injection. Bacteriological examination of the cerebrospinal fluid had revealed the presence of *Ps. pyocyanea*. He accepted the evidence of Mr Hume Kendall that, as the bacillus entered the patient's body from without at the moment of the injection, there must have been some breach of the aseptic technique at the hospital. In this connexion he referred to a paper by Dr Frankis T. Evans and a paper by

¹ Portsmouth Evening News, March 17 to March 26.

'AVLON'

brand

CRYSTALLINE PENICILLIN

(Sodium Salt)

*Enhanced purity, potency
and stability*

Crystalline Penicillin ('Avlon') is characterised by its high standards of purity, potency and stability, and can be relied upon to produce optimal therapeutic effects

- **Highly Purified**—It has a potency of at least 1,600 units per mgm and contains not less than 96% of penicillin G(II)
- **Well Tolerated**—Because of its high degree of purification the possibility of causing pain on injection or of producing untoward reactions in the patient is reduced to a minimum
- **No Refrigeration Required**—'Avlon' Crystalline Penicillin is a stable product and has the advantage that it may be stored at room temperature and retains its full potency for eighteen months

Crystalline Penicillin—'Avlon' is issued in vials of 0.1, 0.2, 0.5 and 1 mega unit

Dr Michael Kremer on meningitis after spinal analgesia which appeared in the *British Medical Journal* of Sept 8, 1945. He was satisfied that the surface skin of the patient was properly cleansed before the operation, and that Dr Hans had prepared himself in the approved way by "scrubbing up" and had done all that was required. The only remaining source of infection was in the apparatus used for the operation. For all of this the nursing staff of the hospital would be responsible, and for any failure by that staff its servants, the corporation would be responsible according to the decision of the Court of Appeal in *Gold v Essex County Council*¹.

He was satisfied that the aseptic technique used at the hospital in 1944 was adequate in the light of the knowledge available at the time, and that there must have been some breach of that technique. The evidence given on behalf of the hospital on that point did not inspire him with great confidence, and the amount of confusion, forgetfulness, and carelessness which had existed was very disturbing. He was satisfied that the origin and sources of the infection were within the control of the hospital and the nursing staff, and that the infection would not have arisen without negligence on the part of the hospital in the care and control of those sources, and must have been due to a breach of the aseptic technique. He could, however, find no evidence that the medical practitioners had been negligent. He accordingly gave judgment in their favour but against the hospital. In the matter of damages, he said that no money could compensate the patient for the terrible disability from which he suffered, and he awarded £12,000 with costs. He granted a stay of execution in view of an appeal.

The defence of Mr Ord and Dr Hans was undertaken by the Medical Defence Union, whose solicitors, Messrs Hempsons, instructed Mr Milford Stevenson, K.C., and Mr Bristow for Mr Ord, and Mr C. R. Havers, K.C., and Mr H. C. Dickens for Dr Hans.

Comment on this case must be deferred until it is known whether or not there is to be an appeal.

HOSPITAL'S LIABILITY FOR HOUSE-SURGEON'S NEGLIGENCE

In the Portsmouth case, as the doctors had not been negligent, the question of the corporation's liability for their doings did not arise. In another recent case, however, it has arisen in an acute form.

In our issue of April 5 (p. 472) we gave a short account of an action in which a widow was awarded damages against the Hertfordshire County Council in respect of the death of her husband from an injection of cocaine given in mistake for procaine. Mr Justice Hilbery found that the surgeon, the student house surgeon, and the pharmacist had been negligent and held that the corporation was liable for the negligence of the house surgeon but not of the operating surgeon. The full report of the judgment² is of interest and importance, for it sets out clearly the present state of the law governing the liability of hospital governors for the acts of their medical staff and carries the law a stage further in development since the Court of Appeal decided in *Gold v Essex CC*³ that a hospital is liable for the negligence of its nursing and medical auxiliary staff in all matters including those involving professional skill. Until that decision it had been supposed on the authority of the judgments in *Hillyer v St Bartholomew's Hospital*⁴ that the hospital's liability covered only 'ministerial or administrative duties such as the summoning of aid in cases of emergency, the supply of proper food and the like,' and stopped short of duties involving professional skill. The present judgment establishes (if it is not reversed on appeal) that hospital governors may also be responsible for the mistakes of a resident medical officer. This is the first decision that has ever held (though the House of Lords came near to it in *Marshall v Lindsey CC*⁵) that a qualified medical practitioner can in the course of his professional duties be the servant or agent of a hospital or other employer. It had previously been held⁶ that the managers of a hospital merely enabled

patients to meet skilled medical practitioners and did not themselves profess to treat patients or pretend that they had knowledge of treatment.

The judge stressed the uncertainty of the law and was conscious that he was exploring new ground. He pointed out that before *Gold's* case it had been generally accepted that the test was whether the hospital officer was performing his duties under a contract for services or a contract of service. If he was working under a contract of service, the hospital was liable, but if under a contract for services as a professional man, it was not. Several decisions have made it clear that a servant, as opposed to an independent contractor, is a person who is subject to direction and control as to the manner in which he shall do his work. The house-surgeon for whose negligence the Hertfordshire Council Council were held liable was a woman student in her last year who had passed some of her final examinations, including that in pharmacology. She was employed as a whole-time resident medical officer on terms set out in an appointment form. The case turned on the obligation that hospital authorities assume in law towards a patient who comes to them for admission and treatment. Lord Greene Master of the Rolls, said in *Gold's* case that once the obligation is discovered, a person accused of a breach of it cannot escape liability because he has employed another person to discharge it on his behalf, and that this is equally true whether or not the obligation involves the use of skill or is one which the governors could never perform themselves. He went on to say 'So far as consulting physicians and surgeons are concerned, clearly the nature of their work and the relationship in which they stand to the respondents [the corporation] preclude the drawing of an inference that the respondents undertake responsibility for their negligent acts. The same may be true of the house-physicians and -surgeons, but their case is not relevant to the present inquiry and I say nothing about it.'

The position of a resident house surgeon was therefore left open for decision. Mr Justice Hilbery took the view in the present case that part of the amenities which the hospital offered to patients was the presence at all times of a resident medical officer, and that his acts done in the course of treatment were acts for which the hospital was responsible. This view, he thought, accorded with the basis of the decision in *Gold's* case, and was the reason why he held the hospital responsible for the house surgeon's mistake.

The hospital's position with regard to the operating surgeon was he considered, quite different. That surgeon was, it was true, not in the same situation as a consulting surgeon, who, according to Lord Greene's dictum in *Gold's* case, does not involve the hospital in liability for his negligence. The judge also found difficulty in the fact that the surgeon had signed a form which spoke of his employment as a temporary part-time employee undertaking to attend on certain hours for a given basic salary. The judge was clear that these were the terms of an employment and was very doubtful whether the hospital was not also responsible for this surgeon's negligence. On the whole, however, he thought that the surgeon's position was such that the authorities could not in any way control how he was to perform his duties. They could not even say what he should or should not do, they could not order him to do an operation, and still less could they say how he should do it. The same was not true of the house-surgeon, to a very great extent the hospital authorities could say how she should perform her work, and indeed did so under a set of regulations which they intended to be binding on her, though these had not been brought to her attention in a way which would make them binding. The hospital was therefore vicariously responsible for the house-surgeon's but not for the surgeon's negligence.

Points of Interest

This decision obviously bristles with difficult and interesting points. The negligence of the house-surgeon was committed in the course of an act which required relatively little professional skill, she made a mistake in transmitting to the pharmacist the surgeon's prescription for an anaesthetic mixture. Would the hospital one wonders, have been liable if she had been negligent in performing a surgical operation? Although the hospital authorities could possibly have ordered her to perform an

⁴ 1942, 2 All E.R. 237

⁵ *Marshall v. Lindsey CC*, 1937, A.C. 97.

⁶ *Evans v. Liverpool Corporation*, 1906, 1 K.B. 160. *Scottish Insurance Commissioners v. Edinburgh Royal Infirmary* (1913) S.C. 751, and others.

operation it is not easy to see how they could control the manner in which she performed it but not the manner in which the visiting surgeon performed the same operation. The fact that she was not qualified and registered was not material to the judge's decision and so if this stands it will establish the liability of hospital governors for the negligent acts of qualified medical practitioners in certain circumstances. Exactly what those circumstances are, and whether the test will be clearly and definitely that of control by the employer remains obscure.

For instance, if in the Portsmouth case the resident anaesthetist had been found negligent (which he was not) would the corporation have been liable?

A less important but still interesting point in the same case concerned the apportionment of the damages between the county council and the surgeon under the Law Reform (Married Women and Tortfeasors) Act, 1935. Before that Act no contribution had been allocable between tortfeasors, each wrongdoer had been severally responsible for the whole of the damages. That Act however, provided that 'the amount of the contribution recoverable from any person shall be such as may be found by the court to be just and equitable having regard to the extent of that person's responsibility for the damage'. If, said the judge, the sentence had stopped at the word "equitable" it would have plainly meant that the court should have the fullest discretion to distribute the damages according to the varying degrees of culpability of the tortfeasors. It is quite a different matter if the court has to decide the extent to which the negligence of one party or the other was causal in bringing about the damage. In the present case the hospital was negligent right up to the injection and even after it, at the same time the surgeon had the duty of checking to see whether what he injected was what he had ordered. He could have done this up to the last moment. The judge therefore felt quite unable to do otherwise than direct that the hospital and the surgeon should share equally in the responsibility and the contributions.

most important health function would lie in the social and preventive side of health work. In Scotland to-day there were more than 250 hospital authorities, and the result was overlapping unnecessary competition, and gaps in the service provided for the patient. There was general agreement that for the future the hospitals needed to be welded together into a single hospital service organized on a regional basis.

Regional Areas

It was clear that local authorities could not be entrusted with responsibility for running the new service, and the duty of providing it should be placed upon a minister responsible to Parliament. The Government therefore proposed that all existing hospitals should be transferred to the Secretary of State for Scotland. Administration was to be entrusted to a special local and regional organization. Regional hospital boards were to be established as agents for the Secretary of State who contemplated that five would be set up in Scotland, based upon Edinburgh, Glasgow, Dundee, Aberdeen and Inverness. Preliminary consultations were in progress about the boundaries of the areas to be covered by each board. The grouping of hospitals under boards of management would be settled by the regional boards themselves. In England certain hospitals were to be designated as teaching hospitals and for them special boards of governors would be appointed who would be directly responsible to the Minister. In Scotland the Government proposed that all hospitals should come within the field of the regional boards, but that the special position of hospitals in which clinical teaching was carried on should be recognized by inclusion in their boards of management of members nominated by the university concerned and by the teaching board. The reason for this difference was that although the number of hospital beds in Scotland was only about one tenth of the total for the United Kingdom, Scotland was training about one third of the total number of medical students. The Scottish Bill placed a duty on the Secretary of State to provide facilities in the hospital service for the teaching of medicine. Responsibility for the conduct of teaching would continue to rest with the universities, who were given a special position in the proposed hospital organization. These proposals had been worked out by the Secretary of State in consultation with representatives of the Scottish universities. The universities were reasonably confident that the provisions of the Bill would enable them to discharge their teaching responsibilities.

In the treatment of voluntary hospital endowments the Secretary of State had followed a plan adopted not long ago for educational endowments and the Bill proposed a Hospital Endowments Commission. The Bill set up a Scottish Health Services Committee with standing advisory committees. These would provide the Secretary of State with expert advice on every aspect of the Health Service, and they would have power to offer that advice on their own initiative.

Direction and Distribution

LORD ROSEBERY said that in the Bill the Secretary of State for Scotland took on himself far more power than was necessary. He was glad, however, that there would be no *ex officio* officers of the Scottish Health Services Council. The Bill went a long way to destroy the independence and prestige of the teaching hospitals. Contrary to the English precedent the staffs of these hospitals were to be nominated by the regional board. That was an unnecessary degradation of the governors of those hospitals. He hoped the Government would relent, so that the hospital staffs would be directly under the hospital management. Clause 35, which dealt with the distribution of medical practitioners, was totally unnecessary in regard to Scotland. Whatever the case might be for direction in England and Wales there was no such case in Scotland. If the service was made free it would attract doctors to the centres of heavy population where the highest reward would follow the latest practices.

He saw no reason why Clause 36, prohibiting the sale of goodwill should be put in to make a further criminal offence. The restriction on the sale of his house by a doctor to another doctor was outrageous and the Clause was practically unintelligible to the layman. It imposed new crimes on doctors who had not the guilty mind which in nearly every crime or the statute book was necessary to a conviction. He hoped the Government would go once more into this Clause and see if they could make it fairer to the medical practitioner. He thought that the appeal from the judgment of a tribunal against a doctor should be to the Court of Session and not to the Secretary of State.

Results of the Plebiscite

LORD SELWICK said the Bill had not been welcomed wholeheartedly by the medical profession, or by many of the boards of governors of hospitals. In the voting which took place at

Medical Notes in Parliament

SCOTTISH HEALTH SERVICE BILL

In the House of Lords, on May 1 Lord MOLLISON moved the Second Reading of the National Health Service (Scotland) Bill.

He said the discussion on the Bill revolved around the ways of achieving an object about which there was little dispute—a comprehensive health service making every kind of health provision available for every member of the community. The case for an overhaul of Scotland's health service was similar to the case in England. The divergences between the two Bills reflected differences between conditions south of the border and conditions in Scotland. Under this Bill a family doctor was to be available for everybody and in all parts of the country there must be means for securing that the distribution of doctors was not so uneven that some areas got a much poorer service than was generally provided. The Bill did this by abolishing the sale of medical practices and setting up a mainly medical body—the Scottish Medical Practices Committee—with power to forbid a doctor to enter practice in the public service in an area where there were sufficient doctors.

The system of remunerations was to include a basic salary which could be varied to attract doctors to areas where their services were most needed. Such an arrangement resembled the system which had been in operation in the Highlands and Islands of Scotland for the past thirty years. In the last generation there had been a trend away from the individual doctor working in isolation towards the partnership system. Along these lines the Government sought to foster the development of general practice. Doctors would be encouraged to work in groups and would be provided with premises designed for the purpose. These premises were the health centres of the future and in Scotland the Bill placed responsibility for providing health centres directly upon the Secretary of State. It authorized him to delegate his functions in this respect to local authorities but he did not intend to do so in the early years of the new service. Responsibility for the local administration of the family doctor service would be entrusted to executive councils composed as to one-half of professional representatives.

The transfer of hospitals from the local authority field would diminish the direct interest of local authorities and of medical officers of health in the treatment of disease. In future their

Scotland on this subject 55% voted against coming into the scheme and 45% were in favour of it. A regional system of hospitalization was inevitable in Scotland, but the position of the teaching staffs should be safeguarded, and at present it was not. The universities were profoundly anxious. They did not even know if they could appoint their own professors of surgery.

The Duke of MONTROSE said that deaf persons wished to be specifically included in the Bill.

Lord TWEEDSMUIR said there were eighty clauses in the Bill but he could not find anywhere a definition of a proper distribution of doctors.

Replying to the debate, Lord MOLLISON said the reception given by the House to the Bill had been beyond his expectations. He was advised that while the staffs of the hospitals would have their contracts with the regional board all but the senior members of the staff would be appointed by the board of management of the hospital and this board would also have a big say in senior appointments.

With regard to hospital endowments, the Commission would be able to place an endowment with the hospital that provided the services. This Bill was based on medical practice by practitioners registered under the Medical Acts. The question of including unregistered practitioners would need amendment of those Acts. But registered practitioners were not restricted in their methods of treatment and private arrangements were not affected by the Bill. The supervisory functions hitherto exercised by the Board of Control in relation to mental hospitals and mental deficiency institutions would in future rest with the Secretary of State. The Board would continue to exercise all its existing functions relating to the liberty of the subject, and to the interests of the patient as an individual and would also supervise private mental institutions not taken over into the new hospital service. The medical members of the General Board of Control and also the medical officers employed by the Board, would at the same time hold appointments as officers of the Department of Health. Under the Bill it would be possible for deaf people not only to be treated for deafness but to be supplied with hearing aids. The deaf-aid apparatus with which the Government was experimenting was not yet ready. He agreed that the medical services in Scotland compared favourably with those in any part of the world but the health of the people in Scotland did not compare favourably with that of people elsewhere. The Bill was an attempt to apply in an organized way in their own country the outstanding medical attainments of the Scottish doctors.

The Bill was read a second time without a division and was committed to a committee of the whole House.

Streptomycin—On April 21 Capt JOHN CROWDER asked the Minister of Health if he would make a statement regarding the clinical trials of streptomycin organized by the Medical Research Council. Mr BEVAN said the trials were in progress and it was not yet possible to foresee the outcome.

Silicosis—Mr D J WILLIAMS, on April 22, asked the number of applications for certificates received by the Silicosis Medical Board from coalminers in South Wales. Mr JAMES GRIFFITHS replied that during January to March, 1946, 2,312 applications were received and 2,424 cases were dealt with by the Medical Board, of which 1,230 were certified to be suffering from pneumoconiosis. The corresponding figures for 1947 were applications received, 1,520, cases dealt with 2,545, of which 840 were certified. Further steps were taken at the beginning of this year to strengthen the staff of the Silicosis Medical Board in South Wales when six new appointments were made two of them to fill vacancies caused by resignation. There were now fifteen doctors attached to the Board in South Wales as compared with eleven a year ago and eight two years ago.

Indian Medical Service—Mr ATTLEE announced on April 30 that the Government of India had informed His Majesty's Government that they were anxious to avoid the loss of experienced officers. They had stated that they were prepared to give to those members of the Secretary of State's Services who continued to serve under the Government in India the same terms as to scales of pay, leave, and pension rights with safeguards in matters of discipline as hitherto. His Majesty's Government had authorized the Viceroy to announce that they accepted the obligation to see that European officers and certain Indian officers should receive compensation for the loss of their careers and prospects consequent on the transfer of power. They undertook also that the members of the Secretary of State's Services in India who retired would be secured in their rights to the leave then due to them. Opportunities would exist for further Government service for many of those who became entitled to compensation. A White Paper which was issued after the Prime Minister's announcement stated that His Majesty's Government accepted a similar obligation to the Indian Medical Service.

Rights of the Subject—The second reading of the Preservation of the Rights of the Subject Bill is set down for May 15 in the House of Lords. This Bill was introduced by Lord READING on April 24.

Naturopaths and Panel Patients—Mr HOUSE on May 1, asked if the Minister of National Insurance had considered the case of a panel doctor at Birmingham influencing the non payment of national health benefit to a Mr Buckingham, and removing Mr Buckingham's name from the list of his panel patients because the latter, immediately following an accident, attended Mr Oldham, a qualified naturopath, and refused to follow the treatment the panel doctor subsequently prescribed. Mr HOUSE suggested an alteration of the regulations to allow naturopaths to certify for National Insurance sickness benefit. Mr STEELE replied that sickness benefit was only payable on proof of incapacity for work. In considering whether this condition was satisfied in a particular case Approved Societies were not tied to the form of evidence they could accept. Mr HOUSE had been advised as to the steps Mr Buckingham should take if he wished to pursue his claim for sickness benefit.

Medical News

A sessional meeting of the Royal Sanitary Institute will be held at 90, Buckingham Palace Road, London, S.W., on Wednesday, May 14, at 3 p.m., when a discussion on "The Control of Small pox" will be opened by Dr W H Bradley.

The annual general meeting of the Westminster Hospital Ladies Association will be held at the Queen Mary Nurses Home of the hospital on Wednesday May 14, at 3 p.m., with the Duchess of Westminster in the chair. The speaker will be the Dowager Marchioness of Reading, chairman of the Women's Voluntary Services, and the secretary of the hospital will give a short talk on "The Future Outlook."

A dinner and dance has been arranged by Queen's University Club, London, at the Dorchester Hotel, W., on Thursday, May 15, at 7.30 for 8 p.m. Members who have not received notices of the above should communicate with the honorary secretary, at 101, Harley Street, London, W.1.

The next quarterly meeting of the Royal Medico-Psychological Association will be held at Barnwood House, Gloucester, on Thursday, May 15, at 10.15 a.m., when, following the business meeting, papers by Dr E L Hutton and Mrs Bassett, on 'Pre-frontal Leucotomy—Effect on Creative Personality,' and Dr R Sessions Hodge and Mr Y Golla, on 'Urethral Smears in Mental Disorder,' will be read. Prof F L Golla will give a demonstration of simultaneous recording of speech and emotional reaction in pre frontal leucotomy and other cases. At 2.15 p.m. there will be a demonstration of apparatus, including electrotoposcopy, at Barnwood House by Dr W Gray Walter, followed by a paper on 'Brain Metabolism' by Dr W R Ashby and a discussion on 'Electric Convulsion Therapy,' to be opened by Prof Golla.

The opening ceremony of Barnett Hill Red Cross House, Woking, Guildford, Surrey, as the national training centre for British Red Cross Society officers will be performed by the Princess Royal on Friday, May 16, at 3 p.m.

Dr Gordon E Richards (Toronto) will deliver the Skinner Lecture before the Faculty of Radiologists at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., on Friday, May 16, at 2.30 p.m. His subject is "The Place of Surgery and of Radiotherapy in the Management of Mammary Cancer—A Study of some of the Factors which determine Success or Failure in Treatment." The lecture is open to all members of the medical profession.

A meeting of the Tuberculosis Association will be held at 26, Portland Place, London, W., on Friday, May 16, at 3.30 p.m., when papers will be read by Dr W Santon Gilmour, on 'Tuberculosis in China,' and by Dr Marc Daniels, on 'UNRRA and Tuberculosis in Europe.'

The annual meeting of the Ophthalmological Society of Australia will be held in Sydney in the first week of September. A cordial invitation is extended to doctors in this country.

Prof A J Ballantyne, Emeritus Professor of Ophthalmology at Glasgow University, received the degree of Doctor of Science from the University of Rowanoke, Salem, Virginia, U.S.A., on April 9.

The Edinburgh University Senate has awarded the Cameron prize in therapeutics for 1947 to Prof Hamilton Fairley.

Dr Ivor Campbell, for a number of years medical superintendent of the West Highland Cottage Hospital, Oban, was the recipient of a gold pocket watch and a cheque on March 5, in recognition of the great services he had rendered to the hospital, and the matron and staff presented him with a set of silver backed brushes and a comb.

A deputation of the British Legion led by Brig-Gen Sir Richard Fitzpatrick drew the attention of the Minister of Health on April 14 to the necessity for hospital facilities for the intensive treatment of rheumatism. The deputation urged that units similar to the British Legion Unit of Rheumatology which was established at the Three Counties Emergency Hospital, Arlesey, Beds, in June last year be set up in selected hospitals throughout the country. The Minister of Health replied that he would encourage the provision of more similar units, and announced that the existing unit would be transferred complete to the Royal Free Hospital.

The Edinburgh Clinical Club has renewed its activities (in abeyance during the war) with a winter series of papers and clinical meetings of special value to general practitioners. Prof Stanley Davidson read a paper on folic acid on March 26 at the last meeting of a successful session. At the annual business meeting Dr A Murray Marr was elected to succeed Dr John Young as chairman for next session.

The increased tax on tobacco will involve the West Riding Mental Hospital Board in an additional expenditure of £12 981 12s to supply tobacco to patients in its hospitals. Last year male patients received a minimum of 1 oz a week and female patients 1/2 oz at a cost of £26,607 4s.

A committee has been formed under the chairmanship of Lord Horder in order to launch an appeal for a memorial to Tudor Edwards. The members of the committee are Lord Dudley, Chairman, Board of Governors, Brompton Hospital, Lord Courtauld Thomson, Chairman, King Edward VII Sanatorium, Midhurst, Sir Max Page, Council, Royal College of Surgeons, Sir Stanford Cade, Westminster Hospital, Dr R A Young, Middlesex Hospital, Dr Geoffrey Marshall, Brompton Hospital, Dr T Jenner Hoskin, Royal Free Hospital, Dr Ivan Magill, Westminster Hospital, Dr Horace Evans, The London Hospital, Dr Geoffrey Todd, King Edward VII Sanatorium, Midhurst, Dr D T Davies, Royal Free Hospital, Hon Secretaries, Mr C Price Thomas Brompton Hospital, Mr F G Rouvray, House Governor, Brompton Hospital. The appeal will be made soon, when the details of its object will be fully stated.

EPIDEMIOLOGICAL NOTES

Smallpox

After nearly a fortnight's interval a further case of smallpox has been reported from Bilston (Staffs). The patient, an unvaccinated labourer aged 69, was taken ill on April 25. A rash developed on April 29 and he was removed to hospital on May 1, where he died the following day. Laboratory tests were positive for variola. This patient was not a contact of any known previous case.

No further cases have been reported from Scunthorpe, Lincs.

Discussion of Table

In *England and Wales* the only infectious disease with an increased incidence was whooping cough with a rise of 366. A fall in incidence was recorded for measles 1,291, diphtheria 31, and dysentery 31.

The rise in the notifications of whooping-cough was general throughout the country, the largest increase was Lancashire 86. Measles was less prevalent in most counties, the greatest decreases were Yorkshire West Riding 291, Leicestershire 173, Warwickshire 158, Middlesex 122, and Derbyshire 109. The only change of any size in the local trends of diphtheria was a decrease of 14 in Lincolnshire. No notable changes occurred in the local returns of scarlet fever. A further 13 cases of dysentery were notified in Surrey, where 25 cases were reported in the preceding week.

In *Scotland* there was an increase in the incidence of whooping cough 253 and measles 73 while a decrease was reported for scarlet fever 51 and cerebrospinal fever 17. The rise in cases of whooping cough and measles was contributed by Glasgow and Greenock. The decrease in the returns of scarlet fever and cerebrospinal fever was fairly general throughout the country.

In *Eire* the notifications of whooping-cough fell by 21, and of diarrhoea and enteritis by 10 in Dublin C.B. Small increases were recorded in the notifications of scarlet fever 8 and diphtheria 4.

In *Northern Ireland* the incidence of measles continued to decline. Only 18 cases were reported from Belfast C.B. during the week.

Week Ending April 26

The notifications of infectious diseases in England and Wales during the week included scarlet fever 892, whooping-cough 2,044, diphtheria 175, measles 7,962, acute pneumonia 647, cerebrospinal fever 64, dysentery 61, paratyphoid 1, typhoid 6.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 19.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London Included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland.

Figures of Births and Deaths and of Deaths recorded under 1 year in infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases. n blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

* Measles and whooping-cough are not notifiable in Scotland and the return are therefore an approximation only.

† Includes primary form for England and Wales. London (administrative county) and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Serum Phosphatase and Cancer of Prostate

Q—What is the significance of the blood phosphatase estimation in carcinoma of the prostate and is there any difference between the acid and the alkaline phosphatase estimations?

A—It has been found that the serum phosphatase which has a maximum activity at pH 5 (acid serum phosphatase) is noticeably increased in carcinoma of the prostate, more especially when bony metastases are present. Acid phosphatase is also increased in the cells of the primary prostatic lesion. After castration the serum acid phosphatase undergoes a sharp reduction towards the normal. The serum acid tests may therefore be helpful in diagnosis and when the patient is taking stilboestrol also of use in regulating treatment. The alkaline phosphatase is of little importance in this connexion. It is difficult to give a figure at which the rise in acid phosphatase becomes significant, as the normal level is different in different patients.

Tapping a Hydrocele

Q—A patient with a hydrocele is not in a fit condition to stand operation. Can you give the formula now in use for injection after tapping and the technique employed in the obliteration of the sac? Does much discomfort or pain accompany this procedure?

A—Authorities are not all agreed as to the advisability of treating hydroceles by aspiration and the injection of irritant fluid. This treatment is more likely to be successful when the hydrocele is thin walled and of only moderate size. Recurrences take place in about 10% of cases. The hydrocele is first tapped in the usual manner and when the last drops of fluid have been expressed a syringe containing the irritant fluid is applied to the cannula. The fluid is then injected and the sac manipulated. Part or all of the fluid is allowed to drain away and the cannula is withdrawn. The following solutions have been used: sodium morrhuate (5 ml of a 5% solution), carbolic acid (1 drachm (4 g) of crystalline carbolic acid kept liquid with the addition of 10% of glycerol), and tincture of iodine. The patient should be kept in bed for twenty-four hours and afterwards on a couch for several days. The reaction may be fairly severe and for this reason repeated tapping as an alternative to open operation is to be preferred.

Threadworms

Q—My children aged 5 and 2 have had threadworms for the last six months. I have treated them with quassia enemata, carbon tetrachloride and gentian violet and also taken the usual precautions against reinfection but there is no permanent improvement. Can anything further be done?

A—The question of a symptomless adult carrier in the family circle should be considered. In rare instances the appendix may be packed with threadworms and any suspicious symptom or sign of appendicular trouble should be considered as an indication for surgery. The use of a rhubarb and sodium bicarb mixture over a period is old fashioned but sometimes very effective in helping the bowel to "throw off" the infection.

Quinine and Otitis Media

Q—Is there any scientific justification for the view that quinine in the usual antimalarial dosage is contraindicated in those subject to otitis media, because of the risk of further impairment of hearing?

A—Otitis media in itself is not a contraindication to quinine in the usual antimalarial dosage. The unpleasant but transitory

aural effects of quinine may, however, be obviated by using one of the new synthetic antimalarial drugs, which at the same time are more satisfactory than quinine in malaria.

Amoebiasis and Appendicitis

Q—Does caecal amoebiasis ever relapse because the infection has been carried on in the appendix? I suggest that even the most thorough treatment with retention enemata and EBI is unlikely to clear a submucosal ulcer possibly protected by debris in the appendix. Would appendicectomy be the correct procedure after a flare-up has been dealt with in the absence of the usual signs of chronic appendicitis?

A—Amoebic infection is unlikely to be confined to the appendix and therefore cannot be considered as the sole source of relapsing infection in the caecum. There is evidence that emetine bismuth iodide is absorbed and does not owe its therapeutic effect solely to surface action, consequently submucosal ulcers respond to standard treatment. Where there is much secondary infection, courses of penicillin and sulphonamides associated with specific amoebicidal drugs may assist in cure. Appendicectomy is not indicated after the treatment of amoebiasis in the absence of evidence of appendicitis. Amoebic typhlitis often simulates chronic appendicitis, but the manifestations rapidly resolve under amoebicidal treatment.

Effect of Chromic Acid on Teeth

Q—Has chromic acid any deleterious effect on the enamel of the teeth?

A—Chromic acid used over a long period can cause staining of the necks of the teeth, followed by some degree of decalcification if the applications are continued long enough. Ulcers of the mucous membrane may also be initiated by careless or over-prolonged administration.

Treatment of Arthritis

Q—What are the indications for gold therapy in rheumatoid arthritis? Is short wave diathermy of value in the treatment of osteoarthritis of the hip?

A—To discuss the indications for gold therapy in rheumatoid arthritis would entail a lengthy article, a modern textbook of the rheumatic diseases should therefore be consulted. Practical experience both of the disease and of the remedy is, however, the only safe guide, and close observation of the effect of each dose including examinations of the urine and blood, is essential. An accelerated erythrocyte sedimentation rate and other evidences that the disease is active are the primary indications for gold therapy. The dose should not exceed 0.05 ml of sodium aurothiomalate, or its equivalent, at intervals of five to seven days. Modern practice is to continue along these lines for fifteen to twenty doses and then to give a small maintenance dose at a longer interval. 0.05 ml once a month would be appropriate, so long as there are no signs of toxicity—albuminuria, skin rashes, stomatitis, leucopenia, etc.

Short-wave diathermy often relieves the pain of osteoarthritis of the hip, but care should be taken to ensure that it is properly focused on the joint. Overdosage must be avoided.

Furunculosis

Q—Can furunculosis be prevented from spreading (a) in the axilla and (b) on the hairy forearm?

A—In the absence of any underlying general cause of lowered resistance, or any local source of infection such as oral sepsis, the spread of furunculosis is commonly due to external irritant factors for example friction, chemicals, including oil or tar and unsuitable and especially greasy or macerating local applications. The objective should be to keep the parts dry, to use dry heat or short-wave diathermy, and local antiseptics that are non-irritant. X-ray therapy is of value, especially in localized furunculosis. Sulphonamides may be given by mouth and penicillin parenterally, but they should not be employed locally.

In furunculosis of the axilla x-ray therapy (150 r unfiltered, at 80 kV, repeated every month for three treatments) may be

recommended in conjunction with treatment along the lines indicated above and with dyes or emamine lotion applied locally. On the hairy forearms the same principles apply. Autogenous vaccines have also been recommended. Non specific shock therapy is often of value as are whole blood injections (10 ml weekly).

Histamine sensitivity

Q—How should I test for histamine-sensitivity? How is desensitization effected particularly in relation to the treatment of Ménière's syndrome in histamine-sensitive patients?

A—To test for histamine sensitivity inject into the skin of the forearm 0.05 ml of a 1 in 10,000 solution of histamine calculated in terms of histamine base. Sensitive patients will react with an urticarial weal almost an inch (2.5 cm) in diameter, having one or more pseudopodia, 1 inch in length with a surrounding erythema of 2 inches (5 cm) or more. In the non sensitive patient the urticarial weal will be about 1/3 inch (0.8 cm) in diameter, will have either no pseudopodia or at the most very small buds, and the erythema will be about an inch in diameter. If in doubt test again with double the dose a few days later. If no pseudopodia appear, then the case is not histamine sensitive.

Histamine sensitive patients should be treated with gradually increasing doses of histamine given subcutaneously. The following is a suggested scheme of dosage: starting with a 1 in 10,000 solution 0.05 ml, 0.1 ml, 0.2 ml, 0.3 ml, and so on up to 0.8 ml, then with a 1 in 1,000 solution, 0.1 ml, 0.2 ml up to 0.8 ml, then with a 1 in 100 solution, 0.1 ml and so on up to a maximum dose of 1 mg, or until symptoms of overdose occur which is not infrequent at a dose of 0.4 to 0.5 mg. The injections are given twice a week until the maximum or the maximum without symptoms, is reached after which this dose is maintained weekly for two months (M Atkinson *J Amer med Ass* 1941, 116, 1753 *Proc roy Soc Med* 1946 39 807). The intravenous administration of histamine 1 mg of histamine base in 250 ml of saline, given over at least one and a half hours, is recommended by Horton for the relief of an acute attack of Ménière's syndrome, and is especially indicated for those who have acute loss of hearing (B T Horton *Surg Gynec Obstet* 1941 72, 417 C H Sheldon and B T Horton *Proc Mayo Clin* 1941 15 17).

INCOME TAX

All inquiries will receive an authoritative reply but only a selection can be published.

Living out Allowances

S E inquires whether payment at £100 per annum made as a living out allowance because there is no residential accommodation in the hospital is liable to income tax.

****** Yes—it is liable. The official who makes the payments is responsible for deducting tax under the Pay as you earn scheme. It is, of course, true that a medical officer living in is not liable on the value of that benefit, but when living out he falls into the general class of employees and as such must bear the cost of living out of his taxed income.

"Family Allowances" and "Wife's Earned Income"

'FATHER' writes—"Family allowance is considered by my Inspector of Taxes to be a part of the earned income of the husband. Should not the allowance legally be considered as a part of the earned income of the wife, and thus in many cases, be covered by the wife's earned income allowance?"

****** No. The point is covered by Sec 27 (2) of the Finance Act 1946 which provides that "payments of benefit under the National Insurance Act, other than maternity grant and death grant, shall be charged to income tax under Schedule E" and further that "no such payment shall be treated by virtue of this subsection as earned income for the purpose of Sec 18 (2) of the Finance Act, 1920 (which provides, in the case of married persons for an increased personal allowance by reference to the wife's earned income), unless it is payable by way of unemployment benefit, sickness benefit or maternity allowance."

This statutory rule is clearly one which was deliberately adopted by Parliament and an attempt to abrogate it would be very unlikely to succeed.

Letters and Notes

Car Sickness in Children

Dr A H MOSFLEY (Warrance New South Wales) writes: There was a question about car sickness in children (Nov 30 1946, p 842). The following simple treatment has been satisfactory with three small children. It was used by the old coach drivers to keep out the cold. A sheet of brown paper under the shirt and coming well up to the base of the neck, and over the abdomen.

Massive Doses of Penicillin

Dr J C JONES (London, SE 25) writes: With reference to the reply under Any Questions? on Nov 30, 1946 (p 842), during the recent measles epidemic I have given 250,000 units of penicillin (calc suspension), and even 375,000 units, to children who developed otitis—children mostly of 5 years or less—which completely cleared up the attacks within 24 hours. In two or three cases at the most has the injection had to be repeated. At the same time or immediately following the penicillin a four days course of "uleron" (crushed tablets in syr solu) to prevent recurrence of the otitis was given. Points of importance are: It is necessary to use a very wide bore needle, so that skin anaesthesia (ethyl chloride freezing) is advisable. It is necessary to cover the point of injection with elastoplast made more sticky by spraying with ethyl chloride. It is advisable to inject into the upper lateral sections of the buttocks, otherwise the only suspension of penicillin will leak out and the effect be lost. The only complication I had was with a child suffering not from otitis but from meningitis. This child was given uleron followed after 2 days with several large doses of penicillin. She cleared up in about a week but broke out into a universal vesicular skin rash in which the vesicles ran together into confluent patches. This looked terribly distressing but the patient did not worry much about it, and it cleared quite up without attention except for large doses of 'calfos'.

Lymphoedema of the Legs

Dr FREDERICK SUTTON (Clifton, Bristol) writes: Your contributor (March 22 p 402) makes no mention of chronic postural oedema in women, which is a common cause of this condition. So little is said about it in textbooks that one not infrequently sees girls or young women who have been sent by doctors to the out patient clinic as obscure oedema. In many there is an obvious peripheral circulatory anomaly such as erythrocyanosis, the lower part of the legs being cold and blue and even showing trophic ulcers at times, especially during the colder months of the year. Some patients, however, show only a rather hard lymphatic type of swelling, often affecting only one leg. In the majority of them there is no previous history of thrombophlebitis or other inflammatory reaction, and careful inquiry suggests that it has developed gradually over a period of time. Very rarely one meets with periodic streptococcal lymphangitis in such cases, which arises because of the circulatory dysfunction and which rapidly subsided with rest in bed and salicylates before the days of modern therapy. At the time of the attack the classical signs of inflammation appear and, in a few,ague like chills with fever occur for the time being. Treatment is very unsatisfactory, though the very severe cyanotic cases may be helped by lumbar sympathectomy. Thyroid, pituitary gland extracts, dienoestrol in large doses and mercurial diuretics have been tried with some temporary success. Physical treatment, such as the wearing of an elastic stocking or fine elastic woven bandages and such measures as massage, diathermy, and especially the daily use of the pulsator are helpful, and, moreover, unless they are employed the ankle region gradually becomes more swollen.

Correction

In the answer to a question about "faecal *B coli*" (May 3, p 625) the statement, "therefore many *B coli* occur which are not faecal, those which are not faecal are widely distributed as animal parasites," is incorrect. It should have read "therefore many *B coli* occur which are not faecal, those organisms which are faecal are widely distributed as animal parasites."

OXYGEN POISONING IN MAN

BY

KENNETH W DONALD, D S C, M D, M R C P

Late Senior Medical Officer Admiralty Experimental Diving Unit Chief Assistant Medical Professorial Unit St Bartholomew's Hospital

PART I

The recent war greatly stimulated the study of human tolerance to various changes in environment. This article confines itself to tolerance to increased tensions of oxygen, though there are other important factors at increased pressures which are not considered here. At sea-level there is an oxygen tension of about 159 mm of mercury, and this is the maximum oxygen tension encountered in any natural environment. The oxygen tension in the tissue spaces of warm blooded animals is from 20 to 40 mm of mercury. In under-water work man, by means of various appliances, breathes gases at the pressure to which he is exposed, this being the first essential of prolonged under-water existence. The second essential is that his respiratory movements must continue within their normal range and with their normal frequency. The third is that the gases to which he is exposed must not be noxious, either at the time of exposure or on returning to normal atmosphere. Under most operational conditions it is preferable that the diver is self-dependent and carries his respiratory gases with him. If he carries air, then this must be expelled from his apparatus after each breath and there is great wastage and exposure to dangerous tensions of nitrogen. If he carries oxygen, this gas can be employed not only for metabolic purposes but for the essential rinsing of the lungs during respiratory movement. Thus no gas is wasted and maximum endurance for a minimum load is possible. It would appear therefore that oxygen is the ideal gas for this purpose, provided it is devoid of toxic effects. It is almost certain that the tissues of man, when breathing oxygen at increased tensions, are exposed to an internal environment which has been previously unknown to living matter, and it is therefore difficult to postulate what the reaction to such tensions would be. Whales, in deep dives, protect their general tissues by the complete collapse of their relatively small lungs and transfer of the gases to the inactive dead space.

The first important contribution to this subject was made by Paul Bert in 1878. His pioneer work has withstood the test of time in a most impressive manner. He showed that oxygen at increased pressures was highly poisonous and that no living matter was exempt. Larks exposed to 15-20 atmospheres of air convulsed and finally died. In a large series of experiments Bert showed that the oxygen tension was the decisive factor in the immediate effect of air or of

any mixture of nitrogen and oxygen. Lorrain Smith (1899) next demonstrated that animals breathing oxygen at moderately high tensions over prolonged periods suffered severe and finally fatal pulmonary damage. An enormous amount of animal experimentation followed, but "L'effet Paul Bert" (convulsant) and "L'effet Lorrain Smith" (pulmonary irritation) remained the cardinal features of oxygen poisoning.

With regard to human experiments, the first recorded were by Bornstein and Stroink (Bornstein, 1910, Bornstein and Stroink, 1912), who breathed oxygen for 45 minutes at 3 atmospheres absolute (ats abs) in the Elbe tunnel without ill effect. In 1912 Bornstein suffered from clonic spasm of the legs while riding an ergometer under similar conditions for 51 minutes. In 1930 the late Dr J S Haldane (Haldane and Priestley, 1935) reported confusion and amnesia in deep-sea air divers at 300 ft (91.4 m), and these symptoms were attributed to the raised tension of oxygen. These effects were proved by Behnke *et al* (1935) to be due to the intoxicant effect of nitrogen at high pressures. Yet as a result of this misconception diving on pure oxygen was limited in the Royal Navy to 2 ats abs (apart from submarine escape). In 1933 two Royal Naval officers, Damant and Phillips, breathed oxygen at 4 ats abs in compressed air. Convulsive symptoms occurred in 16 and 13 minutes respectively. Phillips suffered a major convulsion after being turned on to air but while still at 4 atmospheres pressure (Thomson, 1935). In 1934-6 Behnke and co-workers carried out a series of human experiments. Only two exposures were made at 4 atmospheres, where one subject suffered acute syncope after 43 minutes. The other subject convulsed after 44 minutes. At 3 atmospheres four subjects breathed oxygen for three hours with no demonstrable ill effect. In a second series at this pressure the experiment was continued into the fourth hour, when three subjects suffered abrupt onset of vertigo, nausea, and a sensation of impending collapse. Concentric contraction of the visual field was also demonstrated. These results were published and obtained widespread recognition and acceptance. Throughout the world it was assumed that men at comparative physiological rest, as in these experiments, were safe breathing oxygen for at least 30 minutes at 4 atmospheres, and for at least three hours at 3 atmospheres. In time even the proviso concerning rest was usually omitted. The British finding appeared to have

been unnoticed, or forgotten even in Great Britain. In 1941 J B S Haldane reported a convulsion after breathing oxygen for under five minutes, at a pressure of 7 ats abs, during experiments related to the *Thetis* disaster.

The investigations of oxygen poisoning described here were started in April, 1942 owing to the occurrence of several cases of unconsciousness in oxygen-breathing apparatus at depths and in times which were then considered to be safe. The Admiralty Experimental Diving

of these experiments was to gain a more comprehensive picture of oxygen poisoning in the human. Large groups of subjects were therefore employed, and over 2,000 experiments were carried out. Great care was taken to avoid an heroic or "Jules Verne" atmosphere.

The Marked Variation of Oxygen Tolerance in Man

The first series of experiments to be carried out was to determine the oxygen tolerance of a group of healthy male subjects at a fixed oxygen tension (3.7 ats abs). This series was carried out in a pressure chamber of 100 c ft (2.83 m³) capacity. The subject was seated opposite two observers who were in telephonic communication with those outside. All subjects breathed oxygen at pressure until acute symptoms occurred. Experiments in compressed air have a number of advantages. The subject's state can be easily observed and subjective end-points are less likely. Convulsions are a lesser risk. Oxygen was breathed from a Siebe Gorman "salvus" apparatus. Efficient rinsing out of the subject's lungs was carried out and repeated frequently. A series of analyses, however, showed that even with this regime it was difficult to maintain a concentration higher than 95% of oxygen. In most exposures the pulse and respiratory rates were noted every five minutes. Subjects varied from cooks to recently trained divers, experienced divers, submarine ratings, medical officers, special service operational personnel, and mine disposal officers and ratings. All were Grade A1 in fitness, and ages varied from 18 to 40 years. Experiments carried out in this manner are referred to hereafter as in the "dry," in contrast to those carried out under water and referred to as in the "wet." The results of these experiments are given in Table I and shown graphically in Fig. 4 (in the "dry").

FIG 1—Subject breathing oxygen under pressure

FIG 2—Soft-helmeted counter lung oxygen-diver (Human torpedoes)

(Admiralty Photos)

Unit was created to investigate this and other urgent problems of high-pressure physiology. The main body of human experiments described in this article were carried out between June, 1942, and February, 1943. No experimental dives where men had breathed pure oxygen at toxic tensions under water had yet been reported. The object

23	Lip twitching epigastric aura	6	Severe nausea
20½	Lip twitching twitch L. arm amnesia	6	Severe lip-twitching
19½	Convulsed		

Out of 36 subjects five convulsed, the rest recovered on being turned on to air. The most striking finding was the enormous variation in oxygen tolerance in a group of human beings. Exposures causing marked symptoms at this tension varied from 6 to 96 minutes. The tolerance of each subject was unpredictable. Many attempts to correlate tolerance with age, height, weight, physical fitness, athleticism, smoking, ingestion of alcohol, psychological health, or personality assessments all failed. Symptoms will be discussed in detail later.

The times of exposure causing acute symptoms show a skew type of distribution, notable examples of which are

the response of animals and insects to drugs and hormones. It is clear that the previously reported times of safety at this pressure were dangerously incorrect, in addition, no allowance had been made for individual variation, which is found to be over an enormous range.

Oxygen Tolerance under Water

It has already been emphasized that up to the beginning of these investigations all experiments regarding oxygen tolerance had been carried out by subjects in dry chambers. A series of dives was initiated to discover whether man's tolerance under water was similar to that so far determined in compressed air. The experimental arrangements can be seen in Fig 3, which is self-explanatory. The respiratory apparatus was a modification of the Davis submarine escape apparatus adapted for four hours' endurance. A light rubberized canvas suit with a soft helmet was worn. The diver was submerged in an open tank and tested for leaks, he then walked to the high-pressure tank and was lowered into the water. The upper hatch was closed and air pressure rapidly applied. The diver was thus exposed to the increased pressure but was under water. On the average, subjects were breathing oxygen, mostly at atmospheric pressure, for ten minutes before arriving at the appropriate experimental depth. Time of compression averaged 90 seconds. The temperature of the water was maintained at 65° F (18.3° C). As the depth reading was of the air pressure above the water, the oxygen was breathed at an additional 3 ft (0.91 m) of water pressure (see Fig 3).

FIG 3.—Showing wet pressure chamber with diver under water breathing oxygen in self-contained set. Internal and external

The first series of dives was to 50 ft (15.2 m) (2.5 ats abs) and the time limit was 30 minutes. One hundred different subjects were employed. If the diver convulsed or had severe symptoms he was hauled out of the water and turned on to air. The mouthpiece acted as

an excellent gag during convulsions, and attendants were taught to maintain a good airway. Out of these 100 subjects 26 convulsed, 24 had symptoms, and 50 had no symptoms. Space does not allow details. According to previously accepted figures men were safe breathing oxygen at this depth for at least two hours. The great variability, already demonstrated, makes hard-and-fast rules impossible, but, even allowing for this variation, it was strongly suggested that there was a marked decrease of average tolerance compared with that obtaining in the experiments in compressed air.

A series of dives was therefore carried out to compare the tolerance of subjects in compressed air, and under water, at 60 ft (18.3 m) and 90 ft (27.4 m) pressure of sea-water. In the first series six subjects were employed. At 60 ft in the "dry" the subjects tolerated oxygen-breathing for 180, 120, 120, 158½, 101, and 51 minutes, in the first three cases without symptoms. At the same pressure under water the same subjects experienced acute poisoning in 76, 37½, 25, 61, 19, and 12½ minutes respectively. At 90 ft their performances in the "dry" were 51, 54½, 62, 34½, and 32 minutes, whereas under water they survived only 12, 11, 25½, 18½, and 9½ minutes respectively (one subject indisposed in this series). All these exposures at 90 ft were terminated by acute symptoms. A larger series of "wet" and "dry" experiments at 90 ft is shown in Fig 4. It will be seen from these results that oxygen

FIG 4.—Percentage of subjects eliminated by toxic symptoms at 90 ft (3.73 ats abs) breathing oxygen in compressed air and under water (65° F) in diving suit. No work performed.

tolerance is greatly decreased when the subject is under water. The enormous importance of this finding need hardly be pointed out. The causes of this impairment remain unknown. There is the added 3 ft (0.91 m) of pressure already mentioned, and the diver is breathing pure oxygen in contrast to 95% approximately in the "dry". These two factors are quite inadequate to explain the phenomenon completely. Carbon dioxide accumulation was suspected, as this is known to increase susceptibility to oxygen poisoning in animals (Hill, 1933). Numerous gas analyses negated this possibility. The lack of a rigid helmet, respiratory resistance, the bandaging effect of the suit, the diver's posture, and hydrostatic effects have all been investigated with negative results.

Time-Pressure Relationship for Men Breathing Oxygen Under Water

Next an attempt was made to plot individual curves expressing the relationship of time of survival to pressure. In view of the individual variation it was realized that each diver would have a different curve of tolerance. After a large number of experiments a new factor became increasingly manifest. The tolerance of individual subjects varied from day to day, and it was quite impossible to plot a curve for a single individual. Certain subjects showed this individual variation to a greater degree than others. As with the variation between individuals, no cause for this varying susceptibility to oxygen poisoning could be discovered. In view of these findings, a subject of apparently good resistance was chosen. He dived twice a week over a period of three months to a constant depth of 70 ft (21.3 m) in the "wet" (3.12 atm abs). He wore the same suit and apparatus on all occasions. All dives were carried out about 11 a.m., after an early and light breakfast. His end-points were usually very definite and his health excellent throughout. The results are given in Table II with end-points and

TABLE II—Tolerance of a Single Diver at 70 ft (21.3 m) in the Wet over a Period of 90 Days

FIG 5—Time of exposure causing toxic symptoms in same diver as Table II under sea water at 70 ft (65° F) plotted over a period of 90 days. No work performed.

in Figs 5 and 6. The curve of distribution obtained was very similar to that showing variation of tolerance in a group. Statistical analysis showed that this subject had a

greater variance of toleration than the average. A larger series of experiments confirmed this individual variation. Good examples, in one series, were those divers who survived 100 minutes under water at 50 ft (15.2 m). The averages of all their other performances at this depth were 22, 19, and 15 minutes. One subject, who convulsed after 12 minutes at 50 ft, completed 100 minutes at 50 feet

FIG 6—Percentage of dives terminated owing to toxic symptoms as a function of duration of exposure. Depth throughout, 70 ft of sea water (65° F). Dives over a period of 90 days. No work performed.

FIG 7—Percentage of divers on oxygen, under water, surviving at various times up to 1 hour at 50 ft, 70 ft, 80 ft, 90 ft, and 100 ft of sea water 65° F throughout. No work performed. Actual end points plotted.

without symptoms 16 days later. Six days after this he again convulsed at 50 ft in 32½ minutes. Such findings make it clear that to dive on oxygen to any toxic pressure involves a risk that it is impossible to assess, even if the diver's tolerance has been previously determined.

It now became apparent that the only satisfactory method of assessing oxygen tolerance at various pressures was to employ groups of men for each pressure. Dives were

carried out in the "wet" to a definite end-point by groups of subjects at 50, 60, 70, 80, 90, and 100 ft in an attempt to obtain a clear overall picture. The results are shown in Fig 7. The increased toxicity as the depth becomes greater is clearly shown. The highly skew distribution conforms satisfactorily with the Galton-MacAlister law, and it can be demonstrated that all curves in Fig 7 are the same curve. In other words, the variability of the group is independent of the depth. The coefficient of variation has the huge values of 76-109%, as compared with about 3-4% for such human characters as height, arm length, and alveolar carbon dioxide level. Even more remarkable is the fact that a single diver gave a graph (Fig 6) of the same type with a coefficient of variation of 67%. This means that a single man may be almost as variable as a group, though this is exceptional. Statistical analysis shows that only 40% of the total variation of oxygen divers is accounted for by day-to-day variation of each individual diver. The other 60% is due to variation between the averages of the different divers.

Maximum Non-toxic Depth under Water at Rest

Next an attempt was made to discover at what pressure, under water, oxygen ceases to cause toxic nervous symptoms that would make free diving dangerous. As work is generally known to impair tolerance the investigation was first carried out without exercise. A large number of dives for a maximum of two hours was performed, and toxic symptoms, and even convulsions, were encountered at 40 ft (12.2 m), 35 ft (10.7 m), and 30 ft (9.1 m). The results may be summarized as follows:

Depth (feet)	No of Subjects	No with Symptoms	No Convulsing
40	29	15	4
35	21	6	1
30	20	3	2
25	28	0	0

It is possible that longer exposures may have caused symptoms at 25 ft (7.6 m), but this period is longer than any practical dive on oxygen to this depth. It must be remembered that these divers were exposed to a pressure of oxygen that would occur with a sounding of 32 ft (9.7 m). It is a most surprising finding to obtain oxygen convulsions at as low a pressure as 33 ft (10.1 m) of sea-water (2.1 ats abs). At such a tension the oxygen dissolved in the blood plasma is inadequate for even basal metabolic requirements, and the haemoglobin is still being actively employed for oxygen transport. Gesell (1923) had suggested that the deactivation of the haemoglobin cycle rendered this substance unavailable for carbon dioxide transport from the tissues and that this caused a severe tissue acidosis. Campbell (1930), by his nitrogen injection technique, had confirmed that there was a remarkable rise of tissue carbon dioxide tension at the usual convulsant levels employed in animal work. However, at the minimal tension causing convulsions in these experiments the carbon dioxide tension was shown by Campbell to be hardly raised. It would appear, therefore, that accumulation of carbon dioxide in the tissues is not the essential cause of oxygen convulsions, and this is in accord with more modern research, which will be discussed later.

Effect of Work on Oxygen Tolerance

It has been generally accepted that work diminishes tolerance to oxygen at increased tensions. However, no reliable experimental data are available. *Il Polombaro* (United States Navy, 1938) gives tables showing a marked effect of work, but these figures appear to be merely anecdotal. A further programme of experimental

exposures was therefore carried out in the "wet" with hard work. Controls with the diver resting were also performed. Subjects worked vigorously by lifting a large bag of weights by pulley. Dives were carried out at 50, 40, 35, and 25 ft. These experiments showed conclusively that oxygen tolerance is markedly diminished by work. Figs

EFFECT OF WORK ON OXYGEN POISONING
IN THE WET AT 50 FEET OF SEA WATER
(2.52 ATS ABS)

IN THE WET AT 40 FEET OF SEA-WATER
(2.21 ATS ABS)

Fig 9—Percentage of divers eliminated by toxic symptoms at 40 ft in the wet (2.21 ats abs) during 90 minutes, with and without work. 39 working, 31 not working. Temperature throughout, 65° F.

8 and 9 show the results at 50 ft and 40 ft, with and without work. Even at 25 ft, toxic symptoms occurred in five out of 18 subjects, though no convulsions were recorded.

The physiological reasons why work reduces oxygen tolerance are not at present definitely known. A further increase of carbon dioxide in the tissues is an obvious possibility, though more reduced haemoglobin is available for carbon dioxide transport. The rise of alveolar carbon dioxide, which is probably very marked when exercising on pure oxygen (to be discussed in later publications), presumably causes cerebral vasodilatation, which may be another adverse factor.

Effect of Temperature on Oxygen Poisoning

Previous work had indicated that the lowering of the environmental temperature increased the oxygen tolerance of small experimental animals (de Almeida, 1934, Campbell, 1937). Three series at 50 ft were performed, at 87.5° F (30.8° C) (steam heated), at 45° F (7.2° C) (ice-cooled), and control exposures at 65° F (18.3° C). Divers were allowed to vary their underwear under the suit as the application of this work to operational problems was the first consideration. It is doubted if these exposures could have been tolerated without this variation in clothing. No exercise was carried out. This was advantageous at a higher temperature but disadvantageous to the diver in cold water. The divers complained bitterly of the cold and found the heated dives equally uncomfortable. These experiments showed that oxygen tolerance was equally affected by heat and cold. Although the performances below 30 minutes were only slightly impaired all outstanding performances were eliminated. It is possible that this delayed effect was due to changes in body temperature, as symptoms suggested that this occurred after about 20 minutes.

[To be concluded with a bibliography in next week's issue]

THE NICOTINAMIDE SATURATION TEST

BY

P ELLINGER, Dr Phil, Dr Med, F.R.I.C.

AND

S W HARDWICK, M.D., M.R.C.P., D.P.M.*

(From the Lister Institute of Preventive Medicine London and West Park Hospital Epsom)

Nicotinamide saturation tests have been carried out by numerous workers (Holt and Najjar, 1943, Ellinger and Coulson, 1944, Ruffin, Cayer, and Perlzweig, 1944, Roberts and Najjar, 1944, Coulson, Ellinger, and Smart, 1945, Ellinger, Benesch, and Hardwick, 1945), based on the daily urinary elimination of nicotinamide methochloride and the response to orally administered nicotinamide. These tests are believed to provide information about the nicotinamide state of the tested person, and, indeed, the findings by Holt and Najjar (1943), Roberts and Najjar (1944), Ellinger, Benesch, and Kay (1945), and Ellinger, Benesch, and Hardwick (1945) show a significantly lower nicotinamide methochloride elimination and response to ingested nicotinamide in pellagrins than in physically fit persons. This is remarkable, since the intake, consumption, and storage of nicotinamide, which determine the nicotinamide state of the body, are probably not the only factors responsible for the extent of the elimination of nicotinamide methochloride. Ellinger and Coulson (1944) mentioned the presence of "methyl-donators" and the efficiency of the methylating mechanism as influencing the extent of nicotinamide methochloride elimination. Malabsorption from the intestines was earlier considered as a possible aetiological factor in pellagra (Ellinger, Hassan, and Taha, 1937) and it was proved to affect the response to ingested nicotinamide in pellagrins but not in healthy persons (Ellinger, Benesch, and Kay, 1945). The recent knowledge of the importance of the intestinal flora for the nicotinamide intake (Ellinger, Coulson, and Benesch, 1944, Ellinger, Benesch, and Kay, 1945, Najjar, Holt, Johns, Medairy, and Fleischmann, 1946), the fact that some intestinal bacteria

consume nicotinamide, and the findings by Koser and Baird (1944) that, *in vitro* some strains of *Pseudomonas* and *Serratia*, and by Benesch (1945) that anaerobes from the intestines, also *in vitro* destroy nicotinamide, suggest other factors influencing the response to orally administered nicotinamide. It was desirable to study the influence of these various factors on the response to ingested nicotinamide. Unfortunately the number of cases of various liver diseases was so far not large enough for study of the effect of the methylating mechanism, and experiments on rats with induced liver diseases were not yet conclusive (Ellinger 1946)†. But the effect on the response to ingested nicotinamide of the presence of "methyl-donators" and of the route of ingestion could be studied, and this forms the subject of the present communication.

Experimental

Experiment 1—On 5 healthy persons (2 males, 3 females) and 1 diabetic male, balanced by diet and insulin, of known low methylating capacity (Nos 1-6). The daily nicotinamide methochloride elimination was measured in 24 hour samples of urine for 3 days without extradietary intake of nicotinamide and, on the 4th day, after the oral ingestion of 100 mg of nicotinamide at the beginning of the 4th day's urine collection. On the 5th, 6th, and 7th days no urine was collected. On the 7th to 11th days 1 g of methionine was ingested orally every 12 hours. Urinary nicotinamide methochloride elimination was investigated in 24-hour samples on the 8th to 11th days; no extradietary nicotinamide was administered on the 7th to 9th days and 100 mg of nicotinamide was taken by mouth on the 10th day. The experiment was spread over the second half of 1945. All persons continued with their usual work and had their usual food during the experiment.

Experiment 2—On 5 physically fit inmates of West Park Hospital—1 male and 4 females (Nos 7-11). The urinary elimination of nicotinamide methochloride was estimated for 14 days—the first 3 days without extradietary administration of nicotinamide, the remaining 11 days after daily ingestion of 100 mg of nicotinamide at the beginning of the collection period. In addition, 1 g of methionine was ingested by mouth every 12 hours on the 9th, 10th, and 11th days. The experiment was carried out between March 14 and 31, 1945. All persons in this and the following experiments received the usual hospital diet and were kept in bed or indoors during the experiment.

Experiment 3—On 8 inmates of West Park Hospital—1 male and 7 females (Nos 12-19). Four of these were physically fit; one was a physically fit woman who had suffered from pellagra in recent years, and three were pellagrins. The only differences from Experiment 2 were that every second subject was given the daily 100 mg nicotinamide subcutaneously instead of orally during the whole experiment, while the other half received it by mouth as all subjects in Experiment 2, and the nicotinamide methochloride estimation was continued for one (15th) day after the nicotinamide administration came to an end. The experiment was carried out from April 30 to May 23, 1945.

Experiment 4—On 5 physically fit and 3 pellagrous female inmates of West Park Hospital (Nos 20-27). The arrangements in this experiment differ from those of Experiments 2 and 3 in that nicotinamide was administered throughout the experiment to all persons subcutaneously instead of orally, and that 500 mg (250 mg twice daily) were given instead of 100 mg for all 11 days. Urinary nicotinamide methochloride elimination was measured for 15 days, as in Experiment 3. The experiment was carried out between July 10 and 25, 1945.

Experiment 5—On 9 inmates of West Park Hospital—3 males and 6 females (Nos 28-36). Six of these were physically fit

† Since this paper was submitted for publication experiments have been carried out showing that experimental liver poisoning in rats causes after a preliminary rise in nicotinamide methochloride output due to tissue disintegration, a diminished spontaneous nicotinamide methochloride elimination in urine and a diminished response to dosed nicotinamide. Evidence has been obtained also for the elimination of nicotinamide methochloride in the bile and the destruction of the compound by intestinal bacteria *in vitro* (Ellinger 1947).

* Present address: Medical Superintendent, City of London Mental Hospital, Stone, Nr Dartford.

and three were mild acute or chronic pellagrins. The urinary nicotinamide methochloride eliminations were measured for 15 days. After three days without extradietary nicotinamide administration 100 mg of nicotinamide was given to each person at the beginning of the 4th, 7th, 10th, and 13th days of the collecting period alternatively subcutaneously, orally or rectally. Three people commenced with subcutaneous three with oral, and three with rectal administration and at the end of the course (13th day) ingestion by the first route was repeated, thus each person received ingestion by one route twice and by the other routes once. The experiment was carried out between Oct 28 and Dec 4 1945.

On some occasions the same person was used for more than one experiment, these were Nos 7, 12 (2), 8, 13 (4), 10, 14 (6), 9, 15, 22, 30 (5). Some of them had already been examined in the experiments reported by

administration of nicotinamide. The difference is multiplied as before by 100 and the molar weight of nicotinamide, and divided by the weight in mg of the administered nicotinamide and the molar weight of nicotinamide methochloride.

Discussion

Experiments 1 to 4 (Tables I to IV) should be discussed simultaneously. The pre-dosing nicotinamide elimination of those people who have been examined more than once is remarkably constant over a fairly long period, only the values for the January experiment (Ellinger, Benesch, and Hardwick, 1945) were considerably higher in three instances. In one case—(6) 10, 14—the output varied considerably and was lower in January than on the later occasions. The pre-dosing nicotinamide methochloride

Ellinger, Benesch, and Hardwick (1945). The figures in brackets indicate their numbers in that paper. In all cases collection of urine was done in the same way as described by those authors. The daily urinary nicotinamide methochloride output was measured by the method of Coulson, Ellinger, and Holden (1944).

Results

The results of Experiments 1-5 are shown in Tables I-V respectively. In all tables the pre- and post-dosing elimination of nicotinamide methochloride is presented in mg per day, while the response to ingested nicotinamide—that is, the recovery of nicotinamide—is given as percentage of the ingested nicotinamide. This is calculated by deduction of the daily pre-dosing average elimination of nicotinamide methochloride in mg from the elimination in mg during 24 hours after dosing nicotinamide. This difference is multiplied by 100 and the molar weight of nicotinamide, and divided by the mg of nicotinamide dosed and the molar weight of nicotinamide methochloride. In Table V the recovery for 72 hours after dosing nicotinamide is found by deducting three times the daily pre-dosing average elimination in mg from the sum in mg of the daily elimination in mg for three days following the

elimination was in all instances considerably lower in the pellagrins than in physically fit persons.

The response to a five-day course of 100 mg of nicotinamide was less constant in the fit persons examined more than once, but always much above that of the pellagrins. The response to a daily intake of 500 mg of nicotinamide was not only absolutely but also relatively considerably above that to a daily intake of 100 mg. The relative response to 500 mg was even more increased in pellagrins than in fit persons, so that the difference between pellagrins and non-pellagrins was far less distinct than after the intake of 100 mg. A test with 100 mg of nicotinamide therefore provides a more significant result than one with 500 mg.

So far there has not been much evidence that the presence or absence of "methyl-donators" might influence the extent of nicotinamide methylation and consequently control the height of urinary nicotinamide methochloride elimination. Perlzweig, Bernheim, and Bernheim (1943) observed that in some cases the addition of methionine increased the formation by rat-liver slices of nicotinamide methochloride from nicotinamide. In confirming these results Ellinger (1946a) found that methionine increases the methylation of nicotinamide by slices of liver of those rats

† The amount of NA recovered with 100 mg of NA revealed 1.40% recovery in 24 and 72 hours. The figure in brackets indicates the average of the amount of NA recovered in each of the two periods of 24 and 72 hours respectively.

which had had a low nicotinamide elimination *in vivo*, and had low methylating efficiency *in vitro*. No systematic investigation of the effect of methionine on the urinary nicotinamide elimination by man has so far been carried out.

The limited number of experiments on physically fit persons and one diabetic provide identical results (Table I). No significant change of the daily nicotinamide methochloride output could be observed during a four-day period of oral intake of 2 g of methionine. No significant quantitative alteration was seen in the response to 100 mg of nicotinamide, this in spite of the fact that the second nicotinamide ingestion was made on the fourth day of methionine feeding. This was done to avoid a nicotinamide test during the refractory period, which was observed after methionine intake in some of the other experiments. Unfortunately no pellagrins suited to the experiment were available. The results are, however, so homogeneous that one can conclude that in physically fit people methionine is not a limiting factor for the height of the daily urinary elimination of nicotinamide methochloride or for the response to single doses of 100 mg nicotinamide.

Experiments 2, 3, and 4, described in Tables II, III, and IV, were designed to exhaust, if possible, the body stores of "methyl-donators" by protracted ingestion of nicotinamide. The results vary individually and in the same person at different times to a considerable extent. In the March experiment (Table II) the ingestion of methionine depressed the response very considerably in No 11 and moderately in No 7 and for the first two days in Nos 8, 9, and 10. In the latter three a considerable rise of the response occurred on the third day of methionine intake, which continued for the rest of the nicotinamide intake after discontinuing methionine, on the first of these days the output of No 10 was even higher than the intake, which suggests the storage of nicotinamide. In Nos 7 and 11 an increase occurred only on the second day after the end of methionine feeding.

In the May experiment (Table III) the results on the physically fit people were similar: the extent of the increase was somewhat less high than in the March experiment. In 3 pellagrins (Nos 17, 18, and 19), however, a moderate rise of the response started immediately when methionine intake began and continued over the whole period of further nicotinamide intake. The response of the person who had had attacks of pellagra in recent years (No 16) was intermediate between the fit persons and the pellagrins. It could be expected that an exhaustion of the body from "methyl-donators" would be more pronounced after the daily intake over a longer period of 500 mg instead of 100 mg of nicotinamide.

In 5 physically fit persons (Table IV) the intake of methionine caused already on the first day a considerable increase of the response, which continued to a lesser degree after discontinuing the methionine. The pellagrins, particularly No 27, increased their response to nicotinamide considerably, and differences between pellagrins and non-pellagrins disappeared almost completely. This might be due to the pellagra-curing effect of a dosage 500 mg of nicotinamide for 5 days before the first methionine intake.

To summarize from Experiments 2, 3, and 4 (Tables II to IV) it is evident that methionine increases the response to ingested nicotinamide if relatively large doses of nicotinamide are ingested for a longer period. The effect is far more pronounced after the daily intake of 500 mg than after that of 100 mg. In a nicotinamide-saturation test such as that recommended by Ellinger, Benesch, and Hardwick (1945) with a daily intake for a period of 5 days of 100 mg of nicotinamide the height of the nicotinamide metho-

chloride output might already have been affected by an exhaustion of "methyl-donators".

The most surprising result was the observation of a latent period in the action of methionine of up to 4 days in Nos 7 and 11. An explanation of this phenomenon cannot be given. The oppression of the response to nicotinamide during the first days of methionine dosage suggests perhaps a blocking of the methylating mechanism of the liver.

The development of a nicotinamide deficiency is caused, apart from increased consumption effected by excessive exercise, etc., by insufficient nicotinamide intake from the diet or from the release of the intestinal flora. This can be due to malabsorption or to insufficient production or increased consumption or destruction of nicotinamide by the intestinal flora. Experiment 5 was designed to elucidate this point and to obtain more evidence about the response to nicotinamide when administered by various routes. From the investigation of Ellinger and Coulson (1944) it was known that orally ingested nicotinamide appeared in its methylated form in the urine of physically fit persons a few minutes after its ingestion, that after the intake of 100 mg the elimination peak was reached in about 2 hours, and that the elimination was practically finished after 15 hours. This showed that methylation and absorption were very quick processes and that probably a considerable proportion of the orally ingested nicotinamide had been absorbed from the stomach. Consequently it could be expected that orally and parenterally ingested nicotinamide should give a similar response. It was, however, known from the paper by Ellinger and Coulson (1944) that orally ingested nicotinamide methochloride could be recovered only to a small extent—12–16%—while 62% was recovered after parenteral administration, findings confirmed by Perlzweig and Huff (1946). It was further known that in pellagrins but not in healthy persons the response to nicotinamide is frequently lower after oral than after parenteral application (Ellinger, Benesch, and Kay, 1945). Nothing was known about the fate of nicotinamide given per rectum. Prescott (1945) even doubts, without any evidence, that nicotinamide can be absorbed from the colon. The results shown in Table V provide a great variety of facts which have to be discussed.

1 In most of the 9 cases considered the elimination of the ingested nicotinamide in its methylated form is not finished 24 hours after the ingestion. The difference between 24-hour and 72-hour recovery after parenteral dosage is insignificant or absent on 4, slight on 3, and considerable on 5 occasions, after oral intake the difference is insignificant or absent on 3, slight on 3, and considerable on 6 occasions, after rectal intake the difference is insignificant or absent on 3, slight on 6, and considerable on 3 occasions. Only the considerable differences will be taken into account. If, as is the case with Nos 32, 33, and 35 a considerable proportion of the recovered nicotinamide methochloride is eliminated later than 24 hours after ingestion independently of the route of application, one has to conclude that this is caused by a common factor other than the uptake from the intestines and either that the methylation or the elimination is slow or that part of the ingested nicotinamide is stored temporarily in the body. If, however, a large difference between the 24-hour and the 72-hour recovery is limited to the nicotinamide intake by one route, the mouth (cases Nos 30, 31, and particularly 34), one has to conclude an interference with the nicotinamide uptake from the intestines. There was no large isolated nicotinamide methochloride elimination after the first 24 hours following rectal application.

2 Total response to parenteral and oral application was almost identical in 4 fit persons (Nos 28, 29, 30 and 31) and in 1 pellagrin (No 34). In 2 fit persons (Nos 32 and 33) and 2 pellagrins (Nos 35 and 36) nicotinamide methochloride elimination was far higher after parenteral than after oral ingestion, this indicates an interference with the dosed nicotinamide during its passage through the intestines. It might

due to malabsorption this is however, improbable, since one of these cases showed a delayed elimination after oral ingestion alone. It is more probable that part of the ingested nicotinamide is either consumed or destroyed by the intestinal flora, this assumption is supported by the fact that in all these 4 cases the response to rectal is also much lower than to parenteral administration. In 2 cases (Nos 29 and 31) the response to oral was somewhat higher than to parenteral dosage. This might have been due either to individual fluctuation or to an effect of the previous dosage with nicotinamide during the experiment.

3 In order to find out whether the repeated intake of nicotinamide altered the nicotinamide state of the body and therefore the extent of the response at the end of each experiment a test was made with nicotinamide dosage by the route used at the beginning of the experiment. Considerable rises in response such as in Nos 32, 33 and 36, indicate an improved nicotinamide state in consequence of the repeated nicotinamide ingestions, this is confirmed by the considerably increased daily spontaneous elimination of nicotinamide methochloride in these 3 cases at the end compared with that at the beginning of the experiment. This factor has to be considered when the intermediate responses are valued.

4 In all cases a response was observed to rectally ingested nicotinamide. There can therefore be no doubt about the absorption of nicotinamide from the lower intestines. In most cases (Nos 28, 30, 34, and 35) the response was somewhat but not much lower than that to oral ingestion. In 2 cases (Nos 32 and 33) it was higher than that to oral dosage, and in both these cases there was a considerable rise of the nicotinamide state and response, and this explains the fact. In 3 cases (Nos 31, 36, and particularly 29) the response to rectally ingested was considerably lower than that to orally ingested nicotinamide. This indicates bacterial consumption or destruction, since the whole ingested dose comes in contact with the intestinal flora when rectally applied, while most of the orally ingested nicotinamide is probably absorbed before it reaches the lower intestine and its flora.

Unfortunately it was impossible to obtain for the test more than three cases of pellagra, and all three were very mild cases. Nevertheless they gave a considerably lower response to orally ingested nicotinamide after 24 hours—3.28 mg—as well as after 72 hours—5.35 mg—than the physically fit persons—8.18 and 9.96 mg respectively, and that is the only route which counts for the utilization of dietary and bacterial nicotinamide. From comparing the various values one can conclude that in Case 34, with very much delayed absorption and low response, the nicotinamide state is very low owing to malabsorption. In Case 35, with a delayed elimination after application by all three routes, the methylating mechanism might be faulty and the bacterial supply low on account of the low pre-dosing values and the considerable rise during the experiment. In Case 36, with its low oral response and small delay in elimination, pellagra might be caused mainly by insufficient bacterial supply. In Cases 32 and 33 the difference in response to parenteral and oral intake is considerable and the intestinal destruction of nicotinamide is great, the release of nicotinamide in the intestines must, however, be even higher than the destruction shown by the very high response to the parenteral application. Cases 28 to 31 show no peculiarities except perhaps for the low response of Case 29 to rectally applied nicotinamide. This, however, does not interfere with the normal nicotinamide uptake.

It is still impossible to obtain a complete balance of ingested nicotinamide in man. Small amounts are eliminated in the urine as such, more (between 2.87 and 24.83%) in our last experiment as nicotinamide methochloride. The rest cannot be accounted for. Of parenterally ingested nicotinamide methochloride only about 60% can be recovered. Perlzweig and Huff (1946) and Perlzweig, Huff, and Rosen (1946) believe that part of the nicotinamide methochloride is split up in the liver to unknown products,

and Najjar and Deal (1946) believe in a partial demethylation of nicotinamide methochloride in the liver. Both suggestions are improbable, since Ellinger (1947) could show that rat-liver slices do not destroy nicotinamide methochloride *in vitro*. It is more probable that a portion of the nicotinamide methochloride formed in the liver is eliminated with the bile into the intestine and there destroyed by the intestinal flora like the substance ingested by mouth.* This point cannot be elucidated by our method, but evidence can be obtained of a number of other factors concerned with state, uptake, and utilization of nicotinamide, and this might help to find the cause of a nicotinamide deficiency that might be different in each individual case.

The experiments show that the saturation test as described by Ellinger, Benesch, and Hardwick might be affected by an exhaustion of the "methyl-donators" of the body and therefore not provide a true picture of the nicotinamide state. It might be further affected by factors of the intestinal tract not connected with the nicotinamide state. Parenteral instead of oral application of the test doses would avoid the latter error.

A more satisfactory test, providing more detailed information about a variety of factors concerned with the state and utilization of nicotinamide, can be obtained by the following method. 24-hour urine samples are collected and the urinary nicotinamide methochloride is estimated for 18 days, immediately after the 3rd, 6th, 9th, and 12th collections 100 mg of nicotinamide is administered—subcutaneously on the first and last, orally on the second, and rectally on the third occasion. The recovery percentage of the ingested nicotinamide is calculated for a 24 hour and a 72-hour period and the values obtained are analysed as in these experiments.

Summary

Evidence has been provided that lack of 'methyl donors' may affect the results of a nicotinamide saturation test.

A new nicotinamide saturation test has been described which avoids this error and supplies separate information about the nicotinamide state and the various factors involved in uptake from the gut and utilization of nicotinamide.

We wish to thank Dr W. A. Caldwell for permission to carry out this investigation at West Park Hospital, the nursing staff of West Park Hospital for the careful collection of the specimens and Miss J. Vaughan Morgan for technical help. We are indebted to Dr C. Harrington, F.R.S., for a generous gift of methionine and to Messrs Roche Products, Ltd., for kindly supplying nicotinamide. One of the authors (P. E.) acknowledges with thanks a grant for technical assistance from the Ella Sachs Plotz Foundation, Boston Mass.

TUBERCULOSIS AS A COMPLICATION OF DIABETES MELLITUS

BY

W R GAULD, MD., MRCP

Medical Registrar Aberdeen Royal Infirmary

A LYALL, MD., FRCP

Department of Clinical Chemistry Aberdeen University

During the nineteenth century, when the incidence of and the mortality from pulmonary tuberculosis were much greater than at present, a large percentage of sufferers from diabetes mellitus died of coma, and most of those who survived this died of pulmonary tuberculosis. Publications towards the end of that century indicate that 50% of diabetics succumbed to pulmonary tuberculosis. For example, Windle (1883) reported that of 333 diabetic cases coming to necropsy half had active tuberculous lesions. Naimyn (1906) found pulmonary tuberculosis in 264 out

patients suffering from diabetes over the period 1932-46. Among these were 60 deaths—11 from pulmonary tuberculosis after 1936, with eight such deaths during the war years. A review in 1945 showed that of 657 patients alive at that time 239 were males and 418 females, 12 were under 15 years and 236 between 15 and 45 years of age and 387 were under insulin treatment. The cases considered here are summarized in Table I.

In all cases the patients were definitely diabetic, and the diagnosis of tuberculosis was verified by isolation of the tubercle bacillus. In 11 cases the diabetes preceded the onset of tuberculosis by periods of up to 13 years, while in the other six cases the diagnoses were made simultaneously. Fourteen patients were males and three females. The diabetic condition was detected on an average at 40.18 years of age, and the tuberculosis at 44.23 years. In the greater percentage of cases the tuberculosis made its appearance in the fifth decade whereas the majority of cases of tuberculosis in the general population occur in the second or third decade. This suggests that tuberculosis

of 622 diabetics at necropsy. Despite the passage of the years and even after the advent of insulin in the treatment of diabetes, the incidence of tuberculosis in cases of diabetes mellitus has remained significantly high. This was shown by Baner (1931), who concluded from the available literature that pulmonary tuberculosis was three times commoner in patients suffering from diabetes mellitus than in the general population. These observations were confirmed by Root (1934) when he investigated the incidence of tuberculosis in 1,651 cases of diabetes. The frequent combination of these two diseases is then an accepted fact.

Root (1934) maintains that, despite the decline in the mortality from pulmonary tuberculosis in the general population, the morbidity from tuberculosis among diabetic patients is steadily increasing. This would indicate that the longer the patient has diabetes the greater is the possibility that he will ultimately develop tuberculosis. In view of this and on account of an apparent increase in the incidence of pulmonary tuberculosis among patients attending a diabetic clinic, it was considered important to review the subject in more detail locally.

Review of a Series of Cases

This paper describes 17 cases of diabetes mellitus and tuberculosis encountered during the supervision of 717

developed on account of pre-existent diabetes mellitus. That tuberculosis is a complication of severe diabetes will be seen from Table II. These observations agree with those of Himsforth (1938). Only those cases in which the diabetes preceded the tuberculosis have been used in compiling these figures.

TABLE II

Mild requiring less than 20 units of insulin daily	Cases
Moderate requiring 20-40 units of insulin daily	2
Severe requiring over 40 units of insulin daily	1
	8

All except two patients had symptoms suggestive of tuberculosis some months before the verification of the presence of a tuberculous lesion. Most of those complained of productive cough with loss of weight. Many gave a history of recurrent colds, or perhaps of a head cold which was persistent. Physical signs of pulmonary tuberculosis were present in 14 of the cases at the time of diagnosis.

Table III shows an analysis of the extent of the tuberculous process when first diagnosed and the course of the disease in these cases. The most striking feature is the number of patients with the disease already far advanced at the time of diagnosis. There are several possible reasons for this. The patients were almost without exception under poor or uncertain control, accounting possibly for their greater susceptibility, and also perhaps for the rapid spread

the disease. The majority of the affected cases were most irregular attenders, and adequate checking was almost impossible. The early symptoms of tuberculosis simulate those of diabetes so that errors in diagnosis are easy. And, finally, of course, the physical signs of pulmonary tuber-

eulosis are seldom more than minimal until the disease is well advanced. In six patients the pulmonary disease remains arrested. In point of fact, seven are shown as arrested in Table III, but of these one died of coronary thrombosis.

Discussion

The patient under poor diabetic control is more prone to the complication of tuberculosis. Root (1940) showed that patients who have suffered from coma are the most likely to develop pulmonary tuberculosis. Moreover, he has shown that patients on a free diet yield a far greater percentage of tuberculosis than those subject to careful dieting. It should be remembered, however, that the patients on free diet are on the whole less well-off economically. Consequently, this introduces an environmental element which renders direct comparison between the two groups an unjustifiable procedure. Conversely, Himsworth (1938) in a series of 300 diabetics under good control found that only two developed tuberculosis. These facts are largely borne out in the present series of cases. On the experimental side Steinbach and his colleagues (1935) have produced some evidence to show that dogs rendered diabetic by removal of the pancreas were less resistant to a known dose of tubercle bacilli than a control group of healthy animals. This suggests that the increased susceptibility of the diabetic dogs to the tubercle bacillus may be due to faulty carbohydrate metabolism.

This fact forms the basis of the most frequently accepted hypothesis, which is that hyperglycaemia favours the growth of the tubercle bacillus in the body. Joslin and others (1940) stated that this is due to the hyperglycaemia impairing the normal reparative tissue processes and the resistance to infection—statements which are not accorded universal agreement (Richardson, 1933, 1935). Long (1930) suggested that the primary cause was an upset in fat metabolism with an increased availability of glycerin, which, of course, is one of the best nutrients for acid-fast organisms.

The fact that diabetic coma often leads to the appearance of pulmonary tuberculosis or a flare-up of an already existing lesion is thought to be partly attributable to an over-supply of nitrogenous compounds which favour the growth of tubercle bacilli. In this connexion Keeton (1941) brought forward the suggestion that tissue resistance is lowered by acidosis, and Smithburn (1935) demonstrated experimentally that the virulence of the tubercle bacillus is increased by increasing the acidity of the culture. Furthermore, Root (1934) emphasized the possible importance of the reticulo-endothelial system. In poorly con-

trolled diabetics the cells of this system are often found to be distended with fat, and it is recognized that any interference with these cells causes a decrease in the defence and resistance of the body.

There is another possible factor which has found much favour in recent American literature. It is well known that deficiency of vitamin A leads to specific changes in the mucosa of the respiratory system characterized by atrophy of the epithelium with associated disappearance of the ciliary function, proliferation of the basal cells, and replacement of the original epithelium by stratified keratinizing epithelium. That vitamin A deficiency exists in diabetes has been reported by Brazer and Curtis (1940) and confirmed by Freston and Loughlin (1942). Kimble, Geremek, and Sevringhaus (1946), investigating the vitamin A and carotene metabolism in 116 unselected diabetics, found that 49% of the 59 males and 47% of the 57 females gave values for one or both substances outside the normal range. The predominant type of deviation in the series was low vitamin A and low carotene, and this was particularly noticeable among the older patients and those with infections. A control group of normals, however, also showed variations similar to the above, suggesting that hypovitaminosis A is not likely to be the sole factor, though it might easily be an accessory one. Vitamin A is normally stored in the liver, and its metabolism, as pointed out by Schneider and Widman (1944), is closely coupled with glycogen metabolism in the liver. With the disappearance of hepatic glycogen in uncontrolled diabetes it is obvious that the synthesis of vitamin A will break down with the appearance of hypovitaminosis A.

Prognosis of the Combined Lesions

Study of the mass of literature on the course of pulmonary tuberculosis in diabetic cases discloses a gloomy picture, and without doubt the prognosis is worse than in uncomplicated pulmonary tuberculosis. This may be attributed to (1) the lowered resistance, defence, and repair of the tissues of the poorly controlled diabetic relative to the tuberculous process and its spread, (2) the late stage at which the complication is usually discovered, and (3) complications such as arteriosclerosis, chronic nephritis, and coronary and myocardial degenerations. The prognosis depends on the extent of the tuberculosis when first detected. Since, in the past, the diagnosis has not been established until late it is not surprising that the mortality rate has been high. Lorenzen (1931), for example, reported 143 patients with the combined diseases, and of these only 16 lived more than three years after the tuberculosis was discovered. More recent papers give results which are less pessimistic, and Mark, Mosenthal, and Liu (1942) go so far as to state that it is their impression that with early diagnosis and adequate and careful control of the diabetes the prognosis of the tuberculosis approaches that in the non-diabetic. Certain other writers agree with this.

With regard to the present series 11 out of 17 patients are dead. Of these seven died within the first year, three within two years, and one within three years of the complication being recognized. In two cases the cause of death was coronary thrombosis, and in these cases the chest condition was stationary. In another, death was due to pulmonary embolism—a fortunate escape for a patient whose condition was irretrievable. Of those still alive three are in the critical phase of the first two years, which are well recognized as carrying the highest morbidity.

Treatment

Prophylactic—The earlier the diagnosis the better the prognosis, and therefore continual anticipation of the

possibility of tuberculosis is to be strongly advocated. A diabetic patient beginning to show unusual features, and particularly in our experience recurrent colds or persistent head colds, should be submitted to x-ray examination of the chest, a search for tubercle bacillus in sputum and fasting-stomach contents should be made, and the blood sedimentation rate ascertained. All patients suffering from poorly controlled diabetes, due either to social circumstances or to therapeutic difficulties, should be submitted to radiological examination of the chest every six months, and all other diabetic patients at yearly intervals. Failure to diagnose the combined lesions in the early stages is due to lack of diagnostic consciousness, improper interpretation of symptoms directly or indirectly referable to the chest, and incomplete diagnostic investigation.

Management of Cases—(a) Of the diabetes mellitus. This has evolved through the same changes which have characterized the general trend in the treatment of the disease. Fishberg (1932) stated that patients on low-calorie diet certainly lose their glycosuria, but at the same time there is a rapid progress in the pulmonary tuberculosis. As a result of this a high-calorie diet with moderately high carbohydrate intake is generally advocated. According to Root (1940) the standard diet should consist of carbohydrate, 150 g, protein, 80 g, and fat, 100 g, and a diet to increase weight should include carbohydrate, 250 g, protein, 87 g, and fat, 120 g. The advantages of high carbohydrate intake have been summarized by Keeton (1941) as follows: (1) the appetite is often capricious and carbohydrate is probably more appetizing, (2) fats are not well tolerated and resultant diarrhoea is prone to occur and (3) the ketosis which is so frequently associated with the infection is best counteracted by high carbohydrate intake. Adequate vitamin concentrates should be given if indicated. The indications for the use of insulin are the same as in uncomplicated diabetes. Some authorities (Mosenthal and Mark, 1941) state that the clinical course of the combined lesions is more favourable with protamine-zinc-insulin. On the criteria for control there has been much controversy, but essentially it does not differ from that of the uncomplicated case.

(b) Of the Tuberculosis.—The indications and contraindications for collapse therapy are the same for diabetics as for non-diabetics. Owing to the high percentage of cases showing exudative and fibro-caseous lesions, the accomplishment of an artificial pneumothorax is often unsuccessful and is frequently complicated by pleural effusion and empyema. On the other hand, patients who tolerate artificial pneumothorax well can be considered for ambulatory treatment as in uncomplicated tuberculosis.

Since most cases come under treatment late in the disease, it is not surprising that conservative treatment is the only possible form in many cases. Of this series only four cases were subjected to artificial pneumothorax. In three of these it had to be abandoned because of failure to collapse the affected area of the lung, and the fourth was complicated by tuberculous empyema.

Summary

Seventeen cases of diabetes mellitus complicated by tuberculosis are described.

Poorly controlled diabetes predisposes to tuberculosis and causes a rapid spread of the disease.

This may be due to a complexity of causes.

A high percentage of diabetic patients acquiring tuberculosis are not adequately treated until the disease is far advanced. This calls for a revision of the diagnostic approach to the problem by routine radiography and sputum examinations.

A CASE OF VITAMIN C DEFICIENCY

BY

L. I. HATHERLEY, M.R.C.S.

The following case history presents certain unusual features of vitamin C deficiency and seems to be worthy of record.

Case Report

The patient, a spinster aged 38, employed as a housekeeper, was admitted on June 24, 1946, having vomited blood on three occasions during the previous two days. She volunteered a history of ulcer symptoms extending over six years. These included pain half an hour after meals, which was relieved by taking alkaline powders, and a fear of eating. The symptoms were periodic but had been present during the greater part of the preceding six years. She had adhered to a strict ulcer regime and had refrained from taking fruit and vegetables. A barium meal examination had been made in 1942, but had failed to reveal any abnormality in the gastro-intestinal tract. There was no history of melaena or previous haematemesis even on direct questioning. The bowels were regular and there was apparently no disordered function of the genito-urinary system, though a nephrectomy for tuberculous kidney had been performed in 1928.

The condition of the patient on admission was one of collapse and exsanguination (haemoglobin, 33%—4.6 g %) necessitating an immediate transfusion. After two bottles of blood had been given, her general condition was greatly improved, but the haemoglobin was still only 33%. A further slow transfusion was started, four and a half bottles of blood being given over 36 hours, after which the haemoglobin was only 39%. Twenty-four hours later another transfusion was started, three bottles being given, after which it was found that the haemoglobin had fallen to 28%. On July 1 the patient vomited 1½ oz (14 ml) of altered blood. In view of the dangerously low haemoglobin three more bottles of blood were given and the haemoglobin was raised to 37%.

The patient had now been in hospital for 10 days, and despite the transfusion of 13 pints (7.4 l) of blood, the haemoglobin remained virtually unchanged. There had been no reactions to any of the transfusions, no rigors, no haemoglobinuria, and no sign of jaundice developing to suggest that blood was being lost through haemolysis due to any incompatibility. The stools were black from melaena but were well formed—not loose as though there was severe bleeding from the supposed ulcer at any time. During the 10 days that the patient had been under

ul observation she had vomited only 1/2 oz (14 ml) of J and in view of the ulcer history it seemed probable that the anaemia (which persisted after the transfusion of a greater volume of blood than her own expected blood volume) was caused by a continual loss from a duodenal ulcer and that the amount lost at any one time was not sufficient to regurgitate into the stomach and cause vomiting. Accordingly, the advice of a surgeon was sought, and he thought that the risk of performing a partial gastrectomy on an anaemic patient was in this case justifiable.

At operation the stomach and duodenum were found to be normal there being no evidence of recent ulceration or scarring from a healed lesion. Melaena was present only in the large bowel. There was however slight oedema of the bile duct although the gall bladder appeared normal. The surgeon thought that a streptococcal infection of the gall bladder might be responsible for the oedema of the bile duct and for the bleeding from the intestinal tract. He therefore performed a cholecystectomy and ordered systemic penicillin. In favour of this theory was the intermittent temperature up to 101 F (38.8 C) which the patient had been running during the previous weeks and which in the absence of any physical signs had been thought to be due to the effects of blood in the bowel. The patient appeared to be progressing satisfactorily for the first 48 hours there was no post operative vomiting and the temperature seemed to be settling. On the third day after the operation the patient vomited 4 oz (114 ml) of blood and again on the following day. This time however the blood appeared to be coughed up it was bright and frothy the patient was not nauseated it followed a bout of coughing and the reaction to litmus was neutral. A specimen was sent to the laboratory for spectroscopic examination and was reported to be oxyhaemoglobin and therefore not due to a haematemesis. After a further two days the patient presented the clinical signs of an acute haemorrhage although blood was neither vomited nor expectorated. The haemoglobin fell to 25% (34.5 g %) and the patient became unconscious. Yet another transfusion was begun and three bottles of blood were given slowly before the vein thrombosed. The condition of the patient was somewhat improved although the primary cause of the anaemia was still unknown. It had been proved by laparotomy that there was no ulcer present from which the bleeding could occur, and the theory of a streptococcal focus in the gall bladder being responsible was clearly no longer tenable. Moreover, it had been shown that part of the bleeding was from the lungs. Accordingly other causes of continued blood loss were investigated notably the blood disorders.

The bleeding time was 65 mins and the clotting time 5 mins (capillary tube method). A blood count showed red cells 1,650,000 per cmm, haemoglobin, 35% (49 g %) colour index 1.06 white cells, 20,900 per cmm (segmented polymorphs, 72% non segmented polymorphs 9% eosinophils 1% basophils, 2% lymphocytes, 14% monocytes, 2%). Seven late normoblasts were seen in counting 100 leucocytes. Some Howell-Jolly bodies were present. The red cells showed mild anisocytosis and polychromasia. The platelets numbered 154,000 per cmm. This blood count in itself was not diagnostic and a sternal puncture was performed with the following result.

The bone marrow showed a marked normoblastic reaction. The case was reviewed completely, and on the evidence of (1) the history of restricted diet taken for several years, (2) the absence of any lesion in the gastro-intestinal tract at laparotomy (3) the combined haemoptysis and haematemesis and (4) the blood picture, including the sternal puncture it was thought possible that the patient was suffering from vitamin C deficiency even though the gums appeared healthy. On July 15 in the absence of any more rational line of therapy it was decided to give 1,000 mg of ascorbic acid intravenously. Within half an hour of this injection there was a dramatic improvement in the general condition of the patient. Instead of being weak, apathetic and apparently dying she became alert, bright and cheerful. It was clearly evident that the ascorbic acid had been responsible for effecting an improvement and it was continued by mouth in amounts of 100 mg hourly. From the following morning urine was collected into glacial acetic acid and at the end of a 24-hour period was tested for ascorbic

acid. None was found to be present by the colorimetric method. Hess's sign was positive up to 100 purpuric spots per square inch (15 per sq cm) being counted.

Sternal Tap		
		Limits of Normality
Segmented polymorphs	15.4	0 - 30
Non segmented polymorphs	15.0	20 - 40
Melamycocytes	11.2	2.5 - 12
Myelocytes	5.8	2 - 6
Premyelocytes	0.8	0.5 - 5
Myeloblasts	0.2	0 - 2
Eosinophils	0.0	0 - 5
Basophils	0.0	0 - 1
Lymphocytes	4.8	5 - 20
Prolymphocytes	3.0	
Monocytes	0.0	0 - 5
Plasma cells	0.6	0 - 1
Normoblasts	29.2	7 - 19
{ Late	10.0	
{ Intermediate	0.8	
{ Early	0.4	
Megakaryoblasts	0.0	0 - 4
{ Late	0.2	
{ Intermediate	0.2	
{ Early	0.2	
Pro-erythroblasts	1.2	
Haematocytoblasts	0.2	
Megakaryocytes	0.2	
Mitotic cells	1.0	
Myeloid/erythroblastic ratio	11.1	2.1 to 8.1

On July 18 the urine was again collected for ascorbic acid recovery, and although the patient had had 100 mg hourly for three days, in addition to an initial dose of 1,000 mg intravenously, only 11.25 mg was recovered for the 24-hour period. Even so, the tissues were sufficiently saturated to permit a sum excretion of vitamin C from the urine, but the patient again vomited several small amounts of blood during the day. The haemoglobin was still only 28% necessitating further transfusion, four bottles of blood being given. A blood count now taken showed red cells 2,290,000 per cmm haemoglobin 34% colour index 0.74. The blood film contained a large number of normoblasts not previously demonstrated and suggested a haemopoietic response to ascorbic acid, yet on July 20 the patient again vomited several small amounts of blood though the general clinical improvement which had marked the commencement of vitamin C therapy was still maintained. Next, the possibility of an associated vitamin P deficiency was considered and on empirical grounds 150 mg of hesperidin four-hourly by mouth was given in addition to ascorbic acid. No further vomiting of blood occurred the melaena stools gradually returned to normal and within a week Gregerson's benzidine reaction was given as weakly positive only. During this time the normoblasts disappeared from the blood and a reticulocytosis up to 23% occurred on July 24. An attempt was made to hasten the convalescence by the administration of iron. Ferrous sulphate and iron and ammonium citrate were both tried but were discontinued on account of the dyspepsia which they caused. Colloidal iron was then given and was tolerated very well.

By Aug 7 the patient had been receiving 200 mg of ascorbic acid daily for three weeks, and for the first time the laboratory report indicated that sufficient saturation had been achieved. On iron therapy the blood count improved steadily until Sept 1 when there was a slight deterioration due to a coincident urinary infection. The infection having been treated, the haemoglobin again rapidly increased until on Sept 20 it was 83% and the patient was discharged to convalescence. A month later it was 89%.

Summary

This is apparently a case in which haemorrhage occurred from the gastro intestinal tract and the lungs as a result of vitamin C deficiency and possibly also a deficiency of vitamin P. The patient had previously been treated for a number of years for peptic ulceration, and this together with a fairly typical ulcer history and an unusual presentation of vitamin C deficiency prevented the correct diagnosis from being made earlier in the disease.

I am indebted to the medical superintendent Col Owen Prichard, for permission to publish the case history, and to Dr Morton Gill the visiting physician in charge of this case. I am also very grateful to Dr Signy and the staff of the E.M.S. Pathological Laboratory at Ashford whose friendly help and advice were always readily forthcoming.

"GAMMEXANE" AND MOSQUITO CONTROL

BY

G DAVIDSON, BSc

(From the Ross Institute of Tropical Hygiene)

Field trials with the new insecticide "gammexane" have recently been carried out in Sierra Leone against the adult house-haunting mosquitoes, *A. gambiae*, *A. melas* and *A. funestus* with considerable success. Laboratory tests with gammexane have previously shown that it is not only lethal to mosquitoes in smaller concentrations than DDT but is quicker in its action.

Trials were made in small native villages, first using small smoke generators containing the insecticide, and later using residual sprays. Because of the inadequate retention of the smoke by the ordinary native house the smoke generators did not prove very successful in reducing the numbers of mosquitoes. Residual sprays containing gammexane, applied to the internal walls of the houses, reduced the numbers of mosquitoes in the houses very significantly for periods varying from one to six months, depending on the rate of application of the insecticide, the thoroughness of treatment of the houses, and the proportion of any one area treated. The optimum concentration appeared to be 10 mg of gammexane per sq ft (930 sq cm) of wall surface [4 pints (2.3 litres) of a 0.5% solution of gammexane to 1,000 sq ft (93 sq m)], and the effect produced compared in persistence very favourably with that claimed for DDT at 100–200 mg per sq ft.

Residual sprays made up of gammexane dissolved in kerosene, and water-miscible oil and water-dispersible powder mixtures containing the insecticide, all produced good results, although the latter mixture was slightly less persistent than the other two.

Throughout these trials it was repeatedly observed that the treatment of most of the houses in a village with sprays containing gammexane not only reduced the mosquitoes in the treated houses but also in the untreated ones. Similarly, the treatment of a group of adjacent villages, where a few of the villages were left untreated as "controls," appeared to reduce the density of the mosquito population in the untreated as well as in the treated ones. This would be expected if the result of treatment was to kill off large numbers of the mosquitoes and so reduce the intensity of breeding throughout the area.

It has been suggested recently that the use of residual insecticides in houses causes the normally house-haunting species of mosquitoes to change their habits and to enter houses only to feed, leaving immediately without coming in contact with the insecticide, or resting for such a short time on the treated surface that no lethal effect is produced. As a result of this change in habits no marked decrease in the malaria rate in the local population would be produced by the use of these residual insecticides. Such an argument has been put forward in the case of DDT. Laboratory evidence on the quicker action of gammexane and the evidence accumulated in these trials in West Africa would seem to indicate that this substance does actually kill off large numbers of the mosquitoes, and a consequent reduction in the malaria rate would be expected from its use.

Blood films were taken before and 12 to 22 weeks after treatment of several of the villages involved in these trials, but no significant reduction in the malaria rate was found. It is considered however, that this period is too short for any great change to be produced. It is hoped that further

trials extending over a longer period will be carried out in the near future.

A detailed account of the above trials and their results is to be published shortly.

Medical Memoranda

A Case of Congenital Fibrolipoma of Cornea

The following report of a rare condition is interesting enough to merit publication.

CASE REPORT

A male baby aged 3½ months was brought to the out-patient department of the Wolverhampton and Midland Eye Infirmary as the mother thought "skin was growing over the left eye since birth." There was no history of inflammation or injury. The appearance of the child is shown in the accompanying photograph. The right eye showed normal development. The left eyeball was replaced by a mobile pedunculated rounded swelling about 1½ in (3.2 cm) in diameter. The eyelids and the eyelashes were of normal development and completely covered the eyeball. The cornea and conjunctiva were covered over with a membrane which resembled the skin. A tentative diagnosis of corneal dermoid was made, and the child was kept under observation. Within three months the swelling was getting bigger, so it was decided to operate. Under general anaesthesia the whole mass was removed. The child made an uninterrupted recovery.

The specimen was sent to the Nuffield Laboratory at Oxford and Miss Mann kindly furnished the following report.

'Macroscopically'—The specimen measures 2.5 cm antero-posteriorly and 1.5 cm equatorially. The globe appears to be constricted in the middle, where the conjunctiva was attached. The globe is divided antero-posteriorly, the anterior half consisting of a dense white mass replacing the cornea, behind this is a small vitreous chamber with retina and choroid in position and an imperfectly formed anterior chamber, but no trace of lens. The condition is one of congenital fibrolipoma of cornea.

"Microscopically"—The cornea is replaced by a mass of fibro-fatty tissue, the surface showing squamous epithelium with skin structures (hair follicles and sweat glands). Beneath this is a layer of fibrous tissue, and beneath this again fat and blood vessels. There is a small malformed anterior chamber, lined with Descemet's membrane and endothelium, but no normal iris or lens, though some peculiar colloidal material in the anterior chamber is probably the remains of a malformed lens. Ciliary processes, retina, and choroid are present. There are many rosette formations (common in malformed eyes). The optic nerve is present, and appears almost normal.

Diagnosis—Congenital fibrolipoma of cornea.

My thanks are due to Mr Wyn Green, assistant surgeon at Wolverhampton Eye Infirmary, for permission to publish this case.

Mann Ida (1937) *Developmental Abnormalities of Eye* Cambridge

The National Institute for the Blind point out that the problem of blindness in British tropical Africa is a serious one. In Uganda, for example, the incidence was found by a joint mission of the Colonial Office and the N.I.B. to be 4,187 per 100,000 population (the comparable figure in the U.K. is 191). One of the chief causes of blindness is ocular *onchocerciasis*. Major H. Ridley, who investigated the disease on the Gold Coast, is quoted as saying that it is "not inconceivable" that the disease might spread to temperate lands.

Reviews

TEXTBOOK OF ANAESTHESIA

Anaesthetic Methods By Geoffrey Kaye, M.D., D.A. in collaboration with Robert H. Orion, M.B., B.S., and Douglas G. Renion, M.B., B.S., D.A. (Pp. 706, illustrated 50s) Melbourne Ramsay (Surgical) Pty. Ltd., 340, Swanston Street

This important work, the result of collaboration between three Melbourne anaesthetists, is intended to guide the graduate taking a house appointment, starting private practice in anaesthesia, or reading for the diploma in anaesthesia. The authors attain this object admirably and cover the whole subject with the exception of local analgesia. The advice given is sound throughout, with enough detail to enable techniques to be understood clearly and carried out. The difficulties inherent in multiple authorship have been overcome completely: the style is smooth and contradictions are non-existent. There are, however, two serious errors in the table of standard colours for British gas cylinders on page 276.

Various subjects related to anaesthesia but which most text books ignore are fully considered—for example, there are most useful chapters on blood transfusion and on oxygen therapy. The authors discuss spinal analgesia with a lucidity and moderation noticeably absent from some works. They describe the action of curare well. Unfortunately the dosage given apparently refers to an unnamed American preparation, and gross overdosage would occur if the British preparation 'tubarine' were injected in the amounts recommended. The 188 illustrations are well chosen, most are diagrams specially drawn to show the principles upon which various appliances work. These serve a more useful purpose than the usual photographs of apparatus which make so many books on anaesthesia resemble instrument-makers' catalogues. Mr P. M. Selby has contributed an excellent chapter on legal aspects of anaesthesia. Although this deals with Australian law most of the general principles apply to English common law.

C. LANGTON HEWER

DIET AND THE SKIN

Skin Diseases Nutrition and Metabolism By Erich Urbach, M.D., F.A.C.A. with the collaboration of Edward B. LeWinn, B.S., M.D., F.A.C.P. (Pp. 634, illustrated 50s) London William Heinemann Medical Books 1946

This work should be of value to the general practitioner, for he is often required by his patient to advise on diet in relation to skin diseases—a subject that has always obsessed the lay public and for which war and post-war restrictions have greatly increased their enthusiasm. The association in the mind of the layman is natural enough, for conditions such as urticaria, rosacea, and some cases of acne dramatically illustrate the possibilities; allergy is of topical interest and may suggest obscure relationships of cause and effect over a wide range of maladies. A touch of humbug sometimes colours the outlook of both medical men and laity. However there are certain essential relationships between nutritional and metabolic factors on the one hand and skin health and disease on the other, and it is important that the practitioner should be able to distinguish fact from fiction.

Dr Urbach, after an interesting survey of the historical background sets the main facts out clearly. He discusses the importance of vitamin deficiencies of carbohydrate metabolism of water balance of acid and alkali balance and the essentials of a balanced diet. The first and principal section of Dr Urbach's work is worth studying but the same cannot be said for the section which deals with particular skin diseases and the dietetic and metabolic factors concerned, for here the author has not been sufficiently discriminating. He has cast his net widely and recorded most of the work that has been done, but some of it is valueless and confusing. The enthusiastic research worker often elaborates minor coincidental findings into important causative connexions and Dr Urbach presents everything without sifting the wheat from the chaff. Exclusion of much of the material in this section would improve

the book. A large section on allergy follows the usual line but it does not, in our opinion, discuss the facts adequately.

The work is well produced and freely illustrated. Many dermatologists, however, will consider unduly optimistic the illustrations showing the effects of dietetic control in some common dermatoses such as psoriasis and neurodermatitis. This book is the first of its kind to appear. If used with judgment and in conjunction with other teaching it will prove helpful to the practitioner.

J. T. INGRAM

ALLERGY

Allergy in Practice By Samuel M. Feinberg, M.D., with the collaboration of O. C. Durham and Carl A. Dragstedt, Ph.D. M.D. Second edition (Pp. 838, illustrated \$10.50 or 58s) Chicago The Year Book Publishers Inc. London H. K. Lewis and Co.

This book excels in its account of air-borne allergens. Dr Feinberg was a pioneer and is still a leader in the study of moulds as a cause of asthma and allied disorders. His long chapter on 'Allergy to Fungi' should be most helpful to those specially interested in this field of research—for it is yet hardly more than that, especially in Britain, where very few mycological and clinical studies have been reported.

Mr O. C. Durham, in the chapter on pollens and pollen allergy, covers the published literature from all parts of the world, naturally only a small fraction is directly applicable to Great Britain. His generalizations on pollen dispersal may represent current opinion in America (though he does not quote any authority for them), but they seem to take too little account of modern theories of diffusivity and to emphasize unduly the influence, at a given place, of distant as opposed to local sources of pollen. The new edition includes three new chapters. In one of these Dr Carl A. Dragstedt describes briefly but clearly the role of histamine in anaphylaxis and allergy. The next chapter is devoted to the new antihistamine drugs and their uses in allergic illnesses. The third new chapter tells how Dr Feinberg prepares the extracts he himself uses in skin testing. The text of the rest of the book has been brought up to date though its subject matter in general remains unchanged. The book is a sound and well-presented account of the theory and practice of clinical allergy.

D. A. WILLIAMS

YEARBOOK OF MEDICINE

The 1946 Year Book of General Medicine August 1945–June, 1946. Edited by G. F. Dick, M.D., J. B. Amberson, M.D., G. R. Minot, M.D., W. B. Castle, M.D., W. D. Stroud, M.D., and G. B. Eusterman, M.D. (Pp. 772, illustrated \$3.75 or 21s) Chicago The Year Book Publishers, London H. K. Lewis and Co. 1946

This valuable review, which covers the period August, 1945, to June, 1946, is an excellent reference book and is useful for those who wish to keep abreast of current literature but lack time or easy access to the original articles. The editors' conservative comments are a firm corrective to those who may be too easily impressed by the conclusions of over-enthusiastic writers.

The largest sections of the book are those on diseases of the blood and chest diseases. The latter includes informative articles on the treatment of empyema by the instillation of penicillin combined with systemic administration. Although surgical intervention is often required, healing of the sinus and re-expansion of the lung are much more rapid. It is interesting to note that a substance inhibitory to the tubercle bacillus has been demonstrated in the gastric juice, the pooling of specimens in spite of increasing the amount of material for search decreases the chances of demonstrating the bacillus. The only abstract on streptomycin in pulmonary tuberculosis gives on the whole a discouraging account. In the section on blood diseases there are four articles on the Rh factor. Wiener states that Rh typing should be done when patients receive multiple transfusions and when transfusions are given to women of child-bearing age. Spies's work on folic acid in the treatment of pernicious anaemia and sprue is given due prominence and articles on this subject appear both in the section on blood diseases and in that on metabolism and nutrition. The latter section contains several interesting articles on protein require-

ments in health and disease. Helmut Sprinz emphasizes the importance of protein deficiency rather than vitamin deficiency as a primary factor in malnutrition.

The section on heart disease does not record any great advance in treatment or diagnosis, but there are useful reviews of current opinion on cardiac surgery and methods of digitalization. The use of strict bed rest in cardiac failure and in active tuberculosis is also discussed. The 1946 Year Book gives the impression that many workers, particularly in America, are pausing to evaluate a variety of tests and investigations in the hope of simplifying the diagnostician's task, and that the clinician, though more willing to subject his patient to major surgical procedures, is concentrating on early functional recovery.

M NEWHOUSE

CHEMICAL IDENTIFICATION

Characterisation of Organic Compounds By F Wild, Ph.D., F.R.I.C. (Pp 306 18s) Cambridge The University Press 1947

The amazing development of modern chemistry, especially in relation to biology and medicine, has necessitated a refinement of standards as well as of methods. Although new compounds or factors may be discovered by analogy and elucidated by circumstantial chemical evidence, it is not always realized as Dr Wild reminds us, that "in general the tests classify but do not identify the compound." Qualitative reactions, such as empirical colour tests may be of use in that they guide the bee of research to the flowers, but absolute identification, the only sure basis for chemical knowledge, demands the preparation of pure derivatives with measurable physical characteristics.

In this conscientious and lucid book the author has collected, summarized and described with full practical details the most convenient methods for the identification of individual members of the chief types of organic compounds. The extent of the area covered is shown by the index which contains over 2000 entries and the text is amply provided with tabulations and formulae. The book will be of great value as a work of reference and also a useful guide to the individual research student, for it contains much information that is often required and presents it clearly.

W R FEARON

JAUNDICE

The Differential Diagnosis of Jaundice By Leon Schiff, Ph.D., M.D. (Pp 313 illustrated \$5.50 or 30s) Chicago The Year Book Publishers Inc London H K Lewis and Co 1946

A book whose author discusses the differential diagnosis of a single symptom is liable to be a sketchy review of the disorders to which the particular symptom is common. Dr Schiff has not entirely overcome that defect. In most of his book he gives a conventional account of the morbid processes that cause jaundice: the descriptions are in the main adequate, but since their central theme is necessarily jaundice they sometimes lack proportion—for instance his account of Weil's disease suggests that jaundice occurs in every case. He neglects the pathology of jaundice and relegates his description of its general characteristics to only 13 pages. Details of laboratory methods are described in an appendix but we should have welcomed a fuller evaluation of their significance. The section on radiology contains some excellent diagrams particularly of ampullary and pancreatic carcinoma. Liver biopsy is well described and some illustrative photomicrographs are included.

While parts of the book are informative it is not sufficiently comprehensive for the physician particularly interested in hepatic disease and a monograph on a single symptom cannot appeal to the harassed student. The English is at times uncorrect—*as* for example, when the author writes of cirrhosis of the liver the disease is prone to occur in occupational groups in which there is contact with alcoholic beverages.

R BODLEY SCOTT

Year Book of Medicine is published by Harvey and Blithe 6 Hanover Square London W1 (6d monthly) and edited by Drs F Croxon D. and W R Bell. A few monthly issues have already appeared. As the title suggests, books are the chief interest of this enterprising venture. The Editors also hope to find scope for reporting learned lectures and Short Office Publications.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Muscle Testing By L Daniels, M.A., M Williams, M.A., and C Worthingham, M.A. (Pp 189 12s 6d) Philadelphia and London W B Saunders 1947

An illustrated survey on manual muscle testing used to assess muscular weakness resulting from disease, injury, or disuse.

Week Ends for Henry By Hester Holland (Pp 192 9s 6d) London Hurst and Blackett 1947

An adventure story.

Appendicite et Urologie By L Strominger (Pp 165 240 francs) Paris Masson 1946

A clinical study of the relationship between appendicitis and urological affections.

L'Anesthésie Intra-Veineuse au Pentotal Sodium By Ernest Kern (Pp 92 100 francs) Paris Masson 1946

A short account of the uses, technique, and effects of thiopentone anaesthesia.

Blind Intubation and the Signs of Anaesthesia By J U Human, M.R.C.S., L.R.C.P., L.D.S., D.A. 3rd ed (Pp 230 10s 6d) London H K Lewis 1947

An account of the physiology and signs of anaesthesia, endotracheal technique, and principles of premedication, intended primarily for the newly qualified.

Surgical Note Taking By Charles F M Saint M.D. M.S., F.R.C.S. 4th ed (Pp 106 4s 6d) London H K Lewis 1947

A summarized account of surgical note taking for students and dressers.

Nursing and Diseases of Sick Children Ed by Alvin Moncreiff, M.D. F.R.C.P. 4th ed (Pp 744 30s) London H K Lewis 1947

Intended as a textbook for nurses, this edition includes new material on the sulphonamides, penicillin, and other topics.

Diagnóstico y Terapéutica Quirúrgicos de Urgencia By Dr F Domenech Alsina (Pp 912 No price) Barcelona and Buenos Aires Salvat 1947

Illustrated textbook of emergency surgery and surgical procedures.

The Dentists Register Published under the direction of the Dental Board of the United Kingdom (Pp 346 15s) London Constable 1947

Nutrition in Industry By the International Labour Office Montreal (Pp 177 6s) London Staples Press 1946

An account of wartime measures in Canada, the United States, and Britain to safeguard the nutrition of industrial workers.

Local Anaesthesia Brachial Plexus By R R Macintosh, M.A., M.D., F.R.C.S., D.A. and William W Mushin, M.B., B.S., D.A. 2nd ed (Pp 56 10s 6d) Oxford Blackwell Scientific Publications 1947

Local analgesia produced by injection of the brachial plexus, illustrated with many diagrams and photographs.

Atas do Segundo Congresso Medico Paulista Vols 1 and 2 By Prof Dr C Gama, Dr P A Netto, and Dr O C Gordinho (Pp 653 and 1,035 Cr.\$150,00 and Cr.\$200,00) Sao Paulo, Brazil Edigraf 1945

A collection of papers presented at the Second Congress of the Sao Paulo Medical and Surgical Association.

Psychological Disorders in Flying Personnel of the Royal Air Force (Investigated during the war 1939-45) Air Ministry Publication (Pp 344 7s 6d) London H.M. Stationery Office 1947

Experimental Embryology in the Netherlands, 1940-1945 By M W Woerdeman, M.D., and Chr P Raven, Ph.D. (Pp 132 Florins 650) New York and Amsterdam Elsevier Publishing Company 1946

Papers by various contributors on experiments on amphibious eggs.

The Mind and Death of a Genius By David Abrahamson, M.D. (Pp 228 16s 6d) London Geoffrey Cumberlege 1946

A biography of Otto Weininger by a psychiatrist.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 17 1947

NUTRITION IN GERMANY

The "hunger marches" in Hamburg and Hanover last week lend special interest to a recent survey of the state of nutrition of the urban population in the British, French, and United States Zones of occupation in Germany by a committee of experts,¹ which toured the three Zones in April. It is unfortunate that the committee was not able to see for itself the state of affairs in the Russian Zone. Russian members of the committee and routine surveys in that Zone would do much to dispel the notion that the Russian Zone flows with milk and honey. The committee found that body weight in the adult population had changed little since December, 1946. Children between 6 and 14, old people over 60, and persons consuming only the "normal consumer ration" of 1,500 calories per day were in the poorest state of health and nutrition. A "normal consumer ration" is not sufficient to prevent loss of weight, and the committee suggest that normal consumers have been able on the whole to obtain from extra-legal sources or from the pooling of rations from other members of the family in a higher ration category an additional amount which must provide at least 350 calories per day. It is obvious that most of these additional calories must come from local supplies, that is, from the country districts near to the cities and towns, and the most readily available foodstuffs from which they can be obtained are bread and potatoes. If all were obtained from bread, the extra-legal consumption of bread grain would be about 100 g per day, and, if potatoes, about 500 g per day. Assuming that 10 million people, a modest estimate, were consuming these foodstuffs, the drain on local supplies would be about 30,000 tons of bread grain per month or 150,000 tons per month of potatoes.

Prices vary considerably throughout the Zones. Potatoes in one small town have been quoted at 50 pfennig per kilogram and in others at 5 marks for off-the-ration supplies. In other areas barter transactions alone secure supplies, a sure sign of scarcity and lack of confidence in the currency. The inevitable result of this extra-legal traffic in foodstuffs has been to freeze supplies and to prevent the free transfer of food from the producing areas to the larger towns by the local German Food Administration. The British Zone, which is predominantly urban, is severely affected by this failure of distribution, and no fusion of the Zones will prevent its remaining so while supplies are gravely inadequate. The same hoarding and bartering of food by the producers has been observed in other European countries in times of scarcity. In the first three months of this year at least 130,000 tons of grain have been held back by farmers largely to enable them to

secure consumer goods such as clothing and household utensils in short supply. While this withholding of supplies has worsened the situation, local supplies, even if all were collected and distributed, would contribute only a very small proportion of the food necessary to honour the normal consumer ration. A dangerous situation has now developed. Since the committee rendered its report the bread ration has been halved and the normal consumer ration has in consequence fallen from the official 1,550 to around 1,000-1,100 calories. This reduction, however, is only an official recognition of the fact that the normal consumer ration has not been fully honoured in large areas of the three Zones for some months. Lack of grain shipments has been largely the cause of this deficiency, but supplies of other rationed foodstuff have been reduced also. Imports are necessary but difficult to secure. The problem of supplying Germany is not a Zonal responsibility but one involving the world-wide allocation of food supplies.

With such a background the findings of the committee are by no means surprising. Lack of calories and protein have resulted in loss of weight in normal consumers. Such weight losses, however, have not increased since the last survey in December. Sharing of family rations and extra legal supplies have not prevented a serious failure to gain weight in the children between 6 and 14 years. The need for more milk in this age group is clearly apparent, but it was not available. Old people fared badly. Unable to contribute to the family pool by collecting food in the country and mostly unable to earn enough to purchase supplies at high prices in the towns, they suffered much loss of weight, and in them oedema is widespread. The appearance of oedema in workers below the age of 50 can be attributed only to a serious deficiency in the calorie intake. In spite of the extra food given to these workers they are being called on to expend more energy than is available in their total ration, shared as it is within the family group. Where possible school-children have been given, five times a week at the most, school meals equivalent to about 300 calories. Those over 14 still at school are thus in a better nutritional state than their coevals in industry. The latter are thin and obviously poorly nourished. Babies on the other hand were well developed, but rickets is prevalent in them. Exact figures are not available, but some indication of the prevalence of rickets in Germany in 1939 was provided by a house to house investigation carried out in the months of June and July, 1939, in Frankfurt-on-Main (now in the American Zone). Nearly 800 children were found to have been born in February and March of that year. Of these it was possible to examine 76%—that is, about 600—aged between 2½ and 5 months.² It was then found that just over 80% of the infants examined showed evidence of healed or florid rickets, the principal manifestations being cranio tabies, rickety rosary, Harrison's sulcus, "pot-belly," and muscular hypotonia. E. Graser, who recorded the investigation, suggested that vitamin D should be distributed as a routine to all infants. Dr Graser wrote (*this was in the summer of 1939*) "Whether rich or poor, highborn or lowly, in our city every baby suffers from rickets unless special precautions are taken."

¹ Combined Nutrition Committee (Br/Fr/U.S.) Report of the Seventh Combined Nutrition Survey. April 26, 1947.

² Z. Kinderheilk. 1939, 61, 520. See Annotation. British Medical Journal, 1940, 1, 577.

There is apparently no lack of supplies of vitamin D in Germany at present, but they have not always been distributed or made readily available for infants and young children. The committee has drawn attention to the presence of clinical signs indicative of vitamin deficiencies. These were mainly deficiencies of vitamins A and C. They may be seasonal, but their presence is serious in young children and young adults. It is interesting to record that though the carotene intake and blood levels were normal or high, the body was not able to convert carotene into vitamin A in quantities sufficient for its needs. The nutritional status of heavy workers and underground miners is reasonably satisfactory. Their rations plus the extra food supplies which they can obtain by the points system enable them to maintain normal weights. But there is no doubt that they share the extra ration with their families, and this is reflected in the output of coal from the Ruhr and in unrest among the miners. Tuberculosis—both notifications and deaths—has continued to increase. Comparison with the returns for the corresponding periods of 1946 shows clearly that the rise is a real one and not due only to an unusually severe winter. Other infectious diseases apparently gave no cause for alarm.

It is impossible to predict what will happen during the next three months before the first harvests are available for distribution. There can be little doubt that the reduction in the basic or normal consumer ration which has now taken place will produce more serious effects than the one enforced a year ago. It is unlikely that the children will be seriously affected, because the Hoover Relief Programme for school children will ensure that the most needy will have a good midday meal on five days in each week. The old people and the younger workers in industry will probably suffer most physically. The ration reduction will have, however, a more serious consequence—less tangible but very real. The loss of confidence in the local food administration, which is largely in German hands, will undermine the Allied endeavour to inculcate a sense of responsibility in the local administrations. Widening the margin between the official ration and the amount needed for mere subsistence cannot fail to aggravate the danger—now a reality—of inequitable food distribution and will encourage black market transactions. It must endanger the policy of sharing local food supplies between the Zones and encourage farmers to hold their produce rather than hand it over to the local authorities. Only adequate grain shipments and a bountiful potato harvest in Germany will prevent the winter and spring of 1947-8 from bringing famine and unrest.

The political structures of the British and American Zones differ, and this difference renders effective combined action difficult. In the American Zone the *Länder* (States) have extensive powers of self-government, and the *Länder* Governments, according to *The Times* diplomatic correspondent (May 13), resent interference from the bi-zonal agencies which deal with such matters as transport and food. Those who conducted the Combined Nutrition Survey last month observed that "large supplies of food are obtained by the population from unofficial sources." There is a wide circulation of food by post from rural districts, and in all three Zones members of the Survey observed

people travelling by train with heavy bags of food. This large scale black-market operation ought to be brought to an end by the Germans in the interests of the Germans, but until the economic and political difficulties have been solved the farmers in the American Zone will keep their corn to themselves.

OCCUPATIONAL DISEASE IN REVIEW

The Minister of National Insurance has appointed a committee¹ to review the policy adopted in scheduling occupational diseases under the Workmen's Compensation Acts and to advise on the selection of diseases for insurance under the National Insurance (Industrial Injuries) Act. This Act came on the statute book in 1946 and will become operative during 1948, although the appointed day has not yet been announced. It will replace the present system of compensation under the Workmen's Compensation Acts, which will be repealed. The principle of listing, or scheduling, occupational diseases is to be retained, and under the new Act they will be known as "prescribed" diseases. "A disease may be prescribed if the Minister is satisfied that it ought to be treated, having regard to its causes and incidence as a risk of their (insured persons') occupations and not as a risk common to all persons, and it is such that, in the absence of special circumstances, the attribution of particular cases to the nature of the employment can be established or presumed with reasonable certainty." The Minister must decide at an early date which diseases are to be included within this definition, and so he has set up this committee to advise him.

The first Workmen's Compensation Act became law in 1898. Its importance in industrial legislation was soon evident, and its provisions were widened in the Act of 1906, particularly in regard to occupational diseases. The Third Schedule appended to this Act specified six conditions for which the worker could claim compensation: mercury, lead, phosphorus, and arsenic poisoning, anthrax, and ankylostomiasis in miners. It was realized almost immediately that there were other diseases which could be added to the Schedule, so in August, 1906, the Home Secretary set up a committee "to inquire and report what diseases and injuries, other than injuries by accident due to industrial occupation, were distinguishable as such, and could properly be added to the diseases for which compensation was paid under the Workmen's Compensation Acts." This committee had Mr Herbert Samuel, M.P., now Viscount Samuel, as chairman. The two medical members were the Regius Professor of Physic at Cambridge University and the Medical Inspector of Factories—at that time there was only one medical inspector. The committee took evidence at forty-one sittings in London, Birmingham, Manchester, Swansea, Glasgow, and other industrial cities, it visited many factories, and the medical members examined a number of workers. Before any disease was scheduled the committee applied three tests. Was it outside the category of accidents and diseases already covered by the Act? Did it incapacitate from work for more than one week (the

¹ Members of the committee are Judge E. T. Dale, chairman, with Sir R. R. Bannantine, Mr S. Chapman, Mr C. R. Dale, Dr J. Vaughan Jones, Prof R. E. Lane, Dr E. R. A. Merewether, Mr H. M. Piper, Mr F. Sulwell, Dr A. L. Winner, and Mr F. K. Forrester, secretary.

minimum period for which compensation was payable)? Was it so specific that the causation of the disease or injury by the employment could be established in individual cases? The result was that some sixteen diseases were added to the Schedule, thus enlarging the list to twenty-two in all. Conditions such as poisoning from carbon monoxide, sulphuretted hydrogen, sodium cyanide, and potassium chlorate, as well as "brass-founders' ague," mange, and bottle-makers' cataract, while fully investigated by the committee, were not included.

By 1946 the scheduled diseases² had gradually increased to forty-four, largely on the advice of the Factory Department,³ and included "cataract in glass-workers," Silicosis, asbestosis, and the condition of the lungs known as dust reticulation are not scheduled under the Act in the ordinary way, but power has in the past been given to the Minister to make special schemes for the compensation of workers employed in specified industries or processes who contract one of these diseases as a result of their employment. A number of schemes have been drawn up—for example, the Refractories Industries (Silicosis) Scheme, the Metal Grinding Industries (Silicosis) Scheme, the Various Industries (Silicosis) Scheme, and so on. Here, surely is an opportunity for the new committee to do some tidying up, particularly in linking diseases with industrial processes. In the new Act, as in the Workmen's Compensation Act, there is mention of the pneumoconioses. Dust reticulation, however, is mentioned for the first time.

The Industrial Injuries Act has other implications, some of which were discussed by Stewart⁴ when the Bill was being debated. In establishing a claim for compensation the present procedure is for the worker said to be suffering from a scheduled disease, say dermatitis, to be examined by the examining surgeon. He then receives a certificate stating that he is, or is not, suffering from the disease. Appeal from this decision, by the man or his union, or by the firm through its insurance company, is to a single medical referee, whose decision is final. Neither of these procedures is to be retained. Medical boards and appeal tribunals are to be set up instead. Wisely, the Act allows questions as to temporary disablement to be referred to a single medical practitioner appointed by the Minister, instead of to a medical board. But no one doctor can, as in the past, be both judge and jury. This is fairer to the worker and to the medical profession.

Another important change is that payments will be made by the Ministry of National Insurance from a fund contributed by workmen, employers, and the State. Private insurance in this respect will cease, as will much of the work done now by doctors on behalf of insurance companies. The fund will normally have an annual income of over £25 000 000, and the number of persons employed in industry and covered by the Act, but not necessarily at much risk, is over 18,000,000.⁵ Benefits are of two types: (a) an injury allowance payable for 26 weeks, (b) a disablement pension payable when the man continues to be incapable of work after this period. Future compensation will be based not on loss of earning power but on the character of the

injury, the loss of a finger may leave the earning power of one man unimpaired but seriously interfere with the earning power of another, yet both will receive the same allowance or pension.

An important issue is raised when the rates of benefit under this Act are compared with those under the new National Insurance Act. Persons suffering from injuries and diseases arising out of their employment will receive somewhat higher rates of benefit than individuals disabled by conditions which have not been "prescribed." The fact that there is a difference may give rise to abuse. The sick worker, comparing the two schemes, may try to obtain the more favourable return for his contributions by claiming that his disability was caused by his work, or he may try to prolong his absence beyond the 26-week period and thus qualify for a pension. This will no doubt exercise the minds of the new committee and particularly its medical members to whom the problems of certification are well known. When it appears that a man's disability may have been caused by his occupation, a feeling of resentment against his work and his employer is not infrequently created. This may retard cure and prolong incapacity periods. If a disability is regarded as not due to work (involving perhaps only 10s a week less in benefit) the man is often readier to return to his job, and psychological disturbances do not arise. This is one cogent reason for asking the committee to go carefully before it adds to the list "Aggravation clauses which the trade unions may press for should also be opposed, not necessarily for highly technical or legal reasons but in the direct interest of the workers."

On both sociological and economic grounds, however, the new Act is, on the face of it, a more satisfying document than the Workmen's Compensation Act. For one thing, it deals with prevention, hopefully perhaps, but the fact remains that it creates hope, and it appears to be constructive. Section 73 states that the Minister may promote research into the causes, incidence, and prevention of industrial accidents, injuries, and disease; he may himself employ persons to do this or help other workers financially. Judgment will be suspended until there is evidence of practical implementation of this part of the Act. For example, what is to be the link with the Medical Research Council? Clearly, however, the country cannot afford to pay out vast money benefits without the closest scrutiny of methods of preventing injury and disease. The worker, now a partner in the payment of contributions as well as a potential recipient of benefits, must become as eager a scrutineer as, no doubt, will be the officials of the new Ministry of National Insurance.

TREATMENT OF FILARIASIS

Filariasis due to *W. bancrofti* has long been an unsolved problem in therapy. The highly developed worms in the tissues and the easily demonstrable microfilariae in the blood seemed as if they ought to be vulnerable to suitable chemical compounds. But for many years all therapeutic trials ended in failure, and patients with recurring lymphangitis, elephantiasis and the other sequelae of this infection continued to lack any radical cure. Tests with different substances have been made by many observers ever since Manson fully described the condition. After

PHYSICAL THERAPY OF MENTAL DISORDER*

BY

D W WENNICOTT, FRCP

The full title of this talk was 'Some Reasons for a Personal Prejudice against the So-called Physical Therapies of Mental Disorder'. By representing my ideas in this form I admit that I prejudge the situation. This may be an unscientific approach, but perhaps it is a suitable one in the case of such unscientific methods of treating the disordered mind. My objections are not to the brutality of the methods. Compared with psychiatric illness even a broken back is not much and a broken leg nothing. Moreover with good care these accidents can be so reduced as to be negligible. I of course assume the good faith of those who practise the arts against which I am prejudiced. I know of no case whatever in which I would ascribe the giving of physical therapy to any but the ordinary motives of the practising physician.

Science in Medical Practice

A doctor is consulted because someone suffers. Patients, and especially relatives, demand therapy but the doctor is trained in the scientific method and his job is to apply science. The doctor is asked to cure magically, but he applies science. By so doing he disappoints even if he gives relief to his patient. But he serves the community by being part of a bulwark against superstition. It is open to anyone to go to a quack for magical relief but it is the doctor who is expected to represent science, or objectivity, and to be not afraid to do nothing if science cannot help. Diagnosis is based on scientific knowledge, the basis of therapy should be the same.

Scientific Psychology

A scientific approach to mental phenomena follows on acceptance of the theory that mental disorder is a disorder of emotional development that the basis of mental health is laid down on what is inborn from birth by the course of development of the personality and development of the individual's emotional contacts with external reality. Through Freud's formulations and work especially his method for objective investigation of unconscious phenomena, there has been a steady development of psychological insight.

The development of scientific psychology could briefly be described in three stages: the first bringing understanding of neurotic ambivalence, the second bringing understanding of depression and hypochondria, and the third bringing understanding of the more primitive mental states which reappear in the insanities.

First came the elucidation of the disturbed relationships between people and the disturbances in people of their instinctual functions as a result of their unconscious conflicts. The work was done from the sorting out of love and hate as it emerged in the transference situation. Following this as it appears to me the patient's conscious and unconscious fantasy about himself began to become analysed, his depression and conscious sense of guilt became his sense of something wrong inside himself, and the psychology of hypochondria became the psychology of the results of loving and hating. The incorporation and discharge of objects came into the analytic interpretation. Melanie Klein's work made all this possible and mania as an alternative to depression was seen to be an extreme example of hypomania as a denial of depression.

The new work on depression naturally linked up with the examination of the integration of the personality itself and phenomena of integration and reality appreciation etc. began to be able to be dealt with in the transference developments and to be brought into relation to instincts. These developments have enabled psychology to encroach on the domain of the alienist the doctor who manages the insanity case.

Convulsion Therapy

Along with this steady progress of psychological science there has been a development of the practice of convulsion therapy.

My main objection to convulsion therapy is that it comes as an escape from the acceptance of the psychology of the unconscious and from the implications of the psychological developments of the past fifty years.

It is well known that there are several techniques but from my point of view the electric technique is worse than the others because of the ease with which it can be done. Moreover, electricity has special significance for the unconscious, and paranoid and schizoid persons are well known to mix up the idea of electricity with ideas of magical influence. Such considerations do not necessarily make ECT bad, but they certainly put us very much on guard when we interpret results and when we meet the prejudice in favour of ECT that is common among psychiatrists to day. Whatever the technique, convulsion therapy is empirical. No one has the slightest idea how it works when it does work. It is true that empiricism carries no final objection. However, scientists hate empiricism and regard it as a stimulus to research.

Our responsibility is great. What is done here in England tends to be done blindly in many parts of the world especially where there is no access to libraries or training in psychoanalytic method or free scientific discussion. The sociological ill effect of a therapy has to be considered as well as the immediate effect on individuals.

Theory of Mental Health

The march of psychology, because of psychoanalysis, is towards the completion of the theory of mental disorder as a disturbance of emotional development. The basis of mental health is being laid down in infancy, in the developing relationship between infant and mother, and even in a more primitive way between the infant and his subjective mother, and more primitively still in the infant's self-establishment. The result of this theory is the fruitful one that the prevention of mental disorder is a new task of paediatrics. In contrast, the result of the empirical therapy of mentally ill people by physical methods is a relatively unfruitful one, it is that more and more neurologists must be found who are qualified to give people fits. These are two sociological results that can be compared one with the other.

Many besides myself have deplored the fact that convulsion therapy inevitably leads away from the psychological approach to a biochemical and a neurological one. Convulsion therapy attracts to mental hospitals people with first-rate qualifications for dealing with the complexities of insulin shock and of all the biochemical changes that need study in this kind of work. The physical therapies in general draw to psychiatry physically minded young doctors, and it is always unlikely that men and women who have reached a high degree of postgraduate training on the physical side will be willing or able to start again and to go into psychology at its beginning. Leucotomy in an extreme degree attracts the wrong kind of doctor to psychiatry. To my mind the modern acceptance of leucotomy is the direct result of the acceptance of empirical shock therapy.

If the sociological results of convulsion therapy are bad the sociological results of leucotomy are deplorable. I think leucotomy is the worst honest error in the history of medical practice. In mental hospitals the result of leucotomy is a new accession of power to the neurosurgeon, an unqualified practitioner from the point of view of the psychologist. Let us not be deceived by his very high degree of skill as a neurosurgeon, this having nothing to do with the case. If one deplores leucotomy and its collaterals one must deplore the convulsion therapies that paved the way for it. The feeling against leucotomy is too great to find expression—the general public and doctors alike are too appalled by this application of empirical method to do anything about it. And they are afraid that if they raise objections the psychiatrists will cease to relieve them of the awful burden of insane relatives and patients.

Let me apply the formula I devised earlier on. Now instead of private suffering with demand for magical treatment being met by the doctor who applies science it has become true to say that society suffering (on account of its mentally ill members) leads to the use of the doctor (because of his being supposed to act according to scientific principles) to cover the application of magic. Leucotomy should be a quack remedy, available for those who ask for cures.

*Abridgment of a paper read before the British Psychological Society (Medical Section) on Nov 27, 1946.

From this subject of leucotomy with its irreversible brain changes I come back to convulsion therapy with a feeling of relief. At least here no damage is done (so we blandly assume). If it should turn out that the effects, good and bad, of ECT are, after all psychological effects, no one individual has been finally hurt, and the convulsion subject can still employ psychotherapy if it should come his way. He can even recover spontaneously in the course of time, with good management, if he is so disposed.

Objections to Convulsion Therapy

To condense my views so far expressed I would say I would not give convulsion therapy, because (1) I would not have it done to myself, (2) it draws to psychiatry the wrong kind of doctors, skilled in the wrong way, (3) it undermines the public's justification for relying on doctors to keep their scientific heads in face of the demand for magic, (4) this form of therapy done here in England leads to mass treatments by the same methods of treatment all over the world, (5) physical methods of treatment represent a tendency away from scientific psychology. Here I would like to add a new point—which is that the chief indication for ECT seems to be involuntional melancholia and the lesser depressions.

Now depression is the illness of valuable people. At the borderline depression is the breakdown of people who are overburdened with responsibility or loss. On this side of the line is the valuable person, often a good mother, who burdens herself with too much concern. On the other side is the same phenomenon but less conscious, and this is depression. In depression at least the patient suffers for her own illness. ECT is at present being applied to the valuable people and if this is recognized it no doubt makes the psychiatrist very concerned indeed as to his own suitability for his task. Few of us are innocent of depression and if we have escaped it we may have done so by a contra depressive defence which is more abnormal than the frank depression phase of a patient.

Psychological Effects of Convulsion Therapy

Having thus summarized my prejudice I would like to give my guess as to the future developments in the psychology of convulsion therapy. I think that psychoanalysts and those trained in that sort of way should work at present on the assumption that all the results of ECT—good, bad, and indifferent—are psychological results. The immense field of the psychological effects of the idea of ECT has been seriously neglected. To discuss this it is not necessary to have given ECT to a thousand patients, or indeed to have given any at all. What we need to do is to pool experiences of the feelings and ideas found during analysis of patients who have had convulsion therapy and of patients who are in touch with fellow patients who have undergone convulsion therapy.

Need for Research

I give two lines of approach. The subject that urgently needs research and discussion is that of the patient's conscious and unconscious reactions to (a) the idea of ECT, etc. (b) the experience of submission to convulsion therapy, and (c) the actual fit. Here are some suggestions.

(a) *Reaction to the Idea of being given a Fit*—I suppose a normal person hates the idea. It must be for this reason that psychiatrists do not have fits given to themselves whenever they feel a bit depressed. Anxious people are likely to be able to become frightened at the idea of the fits in the same way as they can become frightened at the idea of anything. In contrast they may be especially brave in relation to the actual experience. Obsessional patients' difficulties are greatly increased when the idea of convulsion therapy is put before them. The organized defence against spontaneity and uncontrol is liable to be strengthened. Obsessional doubt is liable to find a setting in the problem whether to give or to withhold permission. Guilt will be felt whichever line is taken. In organized paranoia the fits are easily felt to be part of the hostile attack that is expected. In one patient, a girl who had a delusion that someone was trying to destroy her brain this form of therapy was felt to be absolute confirmation of her delusion. In cases with thought transference delusions and the fantasies that so readily get mixed up with theories of electrical phenomena and malicious influence it can well be imagined that electrical shock therapy has a special significance.

(b) *Reaction to the Experience of being given Fits*—In cases with a tendency to conversion hysteria a partial knowledge of brain

functioning is easily used in rationalization of paralyses and paresthesiae following convulsion therapy. Depressive people equate the convulsion with dying, and easily feel absolved by having experienced what it is like to meet death. They hanker after convulsion therapy. In some cases each successive convulsion becomes more dreaded, and the last one is equated with death, and recovery from it gives a new lease of life because of the emotional experience. Suicidal impulses can be met by the convulsion. By this seeming experience of death a suicidal patient can use convulsion therapy as an alternative to suicide. This is comparable to the relief that a suicidal patient can get through a genuine suicidal attempt—one from which the patient recovers through successful intervention.

(c) *Reaction to the Fit Itself*—In what may be called *introversion neurosis* the patient has organized a secret inner world in which relationships are good, and this has been done at the expense of trust in the external world in which are placed the bad relationships. It is probable that in these cases the actual fit is felt as a threat to the artificially good inner-world, and in consequence a rearrangement has to take place with less complete secret hoarding of good relationships within.

This approach is tentative and admittedly incomplete, but I give it to indicate the way the results of shock therapy may be examined as psychological phenomena. It is just here that research is most urgently needed. Curiously enough, it is also just here that there is an unwillingness on the part of practitioners of convulsion therapy to investigate. Much of the objection to convulsion therapy would disappear if the mechanism by which results are obtained were understood. The main trouble is that false theories are built around the assumption that the mechanism by which change is brought about is a physical one, and these theories have already paved the way for the wide employment of leucotomy—and who knows what may follow?

Society's Unconscious Reactions to Insanity

I also want to put forward the idea that these physical therapies express society's unconscious reaction to insanity. This is by far the most difficult thing I have to say. I have reason to believe that the good results that can come from these physical therapies depend on this—that by them expression is given in an acceptable (because hidden) form to the unconscious distress society experiences in face of mental illness. By unconscious I really mean unconscious, and I mean repressed and unavailable to consciousness. Massive guilt feelings and fear and consequent hate are roused in people who are concerned with mentally ill persons, and I think this unconscious hate also underlay the cruelty to mental patients that notoriously coloured the management of the insane up to recent times.

Tail-piece

As a last word I would like to say why I have no hope that these arguments will make any sudden difference to the now established practice of psychiatry. Mental disorder can be maddening to nurse. Abolition of shock therapy to-morrow would place on the doctors and nurses of mental hospitals an emotional burden which they could not suddenly take and there will be those who claim that this alone justifies the method. I see this argument, and respect it. Nevertheless there seems to be a need for someone to register a strong objection to easy and seductive methods which tend to lead away from the difficult path that must be walked by those who try to understand human nature and to eschew magic.

The Psychoanalytic Clinic for Training and Research of the Department of Psychiatry, College of Physicians and Surgeons, Columbia University 630 West 168th Street New York offers a three-year graduate residency training programme in psychoanalytic medicine to qualified physicians. The programme is based on the student's analysis and on hospital and clinic material for psychoanalytic work and includes lectures on Freud's work, psychodynamics, psychosomatics, experimental analysis of animal behaviour, technique, growth and development, comparative analysis of cultures, methodology and theoretical and practical training in psychiatry. Upon fulfilment of the training requirements students will be awarded a certificate of training in psychoanalytic medicine. Those students who in addition undertake satisfactory research and pass a supplementary examination in the related basic sciences may also be awarded the degree of Doctor of Medical Science. Applications for training are accepted throughout the year.

BRITISH ASSOCIATION AT DUNDEE

The first annual meeting of the British Association for the Advancement of Science to be held since the outbreak of war cut short the Dundee meeting in 1939 is to take place again at Dundee, from Aug 27 to Sept 3. Sir Henry Dale the president has announced that in order to emphasize the positive contribution of science to human progress the programme would conform to the general theme of 'Swords into Ploughshares'. His own address under the title 'Science in War and Peace' and the other lectures and papers would be devoted to reviewing the wartime achievements of science and their application to peacetime purposes. Before the war the meeting of the British Association was the outstanding occasion for the publication of scientific achievement. Unlike specialist scientific societies it sought a public platform while still maintaining a high level of presentation and discussion. There have been occasions when important discoveries have been first announced at British Association meetings, though Sir Henry Dale did not know that that was likely to occur on this occasion but war, he said has given an artificial stimulus to scientific development, and the Association has an enhanced function in making people conscious of scientific advance and its possibilities for the community.

Thirteen sections have been arranged. Those of physiology, psychology and anthropology, are to be presided over respectively by Prof Winifred Cullis, Dr S. J. F. Philpott and Prof C. Daryll Forde. In the Section of Physiology there will be discussions on aviation physiology and on climate and health. The Sections of Physiology, Psychology and Education are to combine for a discussion on 'Men and Machines'. Insecticides is the subject of discussion in the Sections of Chemistry, Zoology and Agriculture, and the Sections of Chemistry, Physiology and Botany will unite for a discussion on penicillin and other antibiotics. The new physics will be explored in discussions on the peacetime applications of nuclear fission and on the use of tracer elements stable and radioactive in biology and chemistry. UNESCO is down as a subject for the Section of Education and there is to be a special meeting of all sections for a discussion on 'The Education of the Man of Science'. During the Dundee meeting the Division for the Social and International Relations of Science which arranged a number of important conferences in London during the war, will hold a session on a subject yet to be selected.

A number of scientists have been invited from foreign countries. Three thousand delegates attended the meeting in 1939, and it is hoped that this number will at least be equalled.

SEA AND AIR PORT HEALTH AUTHORITIES ANNUAL MEETING

The Association of Sea and Air Port Health Authorities of the British Isles held its forty-eighth annual meeting at Belfast on May 13, 14 and 15, under the presidency of Councillor S. K. Henry, chairman of the Belfast Port Health Committee. The delegates were welcomed by the Lord Mayor of Belfast, Alderman W. F. Neill.

Presidential Address

Councillor Henry said the association was originally formed in 1898 on the suggestion of Hull and Goole with the support of six other port sanitary authorities. The membership now included medical and lay representatives from all the principal sea and air port health authorities in the British Isles. Among the more important matters considered by the association in the past year had been the improvement of crews accommodation, control of imported foodstuffs, hydrogen cyanide regulations and the effect of the National Health Service Act on the work of port health authorities. The practice of consultation with the Ministries on impending legislation had been continued and Councillor Henry emphasized the importance of uniformity throughout the sea and air ports.

Port Administration in Glasgow

Sir Alexander MacGregor referred to the influence of the association in raising the status of port administration. Discussing the 'convention' diseases, he said that the risk of

spread of plague by shipping had been almost eliminated by the world wide attack on rats in ships, begun after the International Sanitary Convention of Paris (1926). But at Glasgow as at New York, there had been an increase during the war. Vigilance must be maintained, since plague might appear again as it did in 1896 and the following years.

Smallpox had frequently invaded this country in recent years but had never obtained a real foothold. Whether it had died out because of a rapid loss of capacity to infect or because of the precautions taken was an open question. Experience of the Glasgow outbreak of 1942 had led him to discard the one-stroke in favour of the three stroke vaccination, and to pay particular attention to the revaccination of those contacts in whom the first attempt at protection had been unsuccessful.

Recent advances in the construction of crews quarters were worthy of note. A big step forward had been taken by the Board of Trade in its instructions to surveyors in 1937 and 1944. Vessels were being built on the Clyde and elsewhere with high standards of design and equipment for the health and comfort of the crew. Good construction implied good housekeeping on board, in which the co-operation of the seamen was essential. He advocated for officers a short course of instruction in ship hygiene, food, first aid, and the treatment of venereal disease. Seamen of whatever nationality should be assured of prompt and convenient hospital or outdoor treatment at the major ports as part of a joint welfare and medical service.

International Health

Dr Melville Mackenzie outlined the work of the Pan American Sanitary Bureau, of the Office International d'Hygiene Publique, and of the Health Organization of the League of Nations. He described the creation and achievements of UNRRA, many of the functions of which had been taken over by the Interim Commission of the World Health Organization. The World Health Organization had also set up expert commissions on the nomenclature of the causes of morbidity and death, habit forming drugs, malaria, biological standardization, epidemiological work, post-vaccinal encephalitis, the immunity reaction in smallpox, venereal diseases, and other subjects.

Crews' Quarters and Food

Dr T. Lloyd Hughes said that for many years the standard of accommodation in British ships had often been much inferior to that found in vessels of some of the foreign countries, particularly the Scandinavian. Instructions issued by the Board of Trade in 1937 together with those published by the Ministry of War Transport in 1946, insisted upon a higher standard and had resulted in many improvements. Even so, there was need for further legislation. He suggested that the crews quarters should be as good as this allowed for a better lay out than was possible when the quarters were situated forward. Individual cabins were desirable but in any case no more than four members should share a cabin, and there ought to be separate accommodation for each watch. Bunks should be made of polished wood without cracks or crevices, to avoid bug infestation.

Dr Hughes condemned the use of coal stoves as being both dangerous and dirty and recommended hot water radiators. Ventilation of the quarters was important, and forced draught ventilation was the method of choice. The provision of cupboards, wardrobes and comfortable furniture would improve the living conditions of merchant seamen. There should be running hot and cold fresh water for officers and crew alike with ample provision of shower-baths. Laundry facilities and separate mess-rooms with specially appointed stewards were long overdue amenities.

Concluding, Dr Hughes drew attention to the fact that the inspection of ships' provisions was the responsibility of the Ministry of Transport. The services of the trained port health food inspectors had not been utilized. In his opinion this responsibility could, and should, be passed over to the port health authorities.

Sanitary Control of Foreshores

Dr S. Barron described the public health problems met with in the early years of the present century in connexion with the sanitary control of the foreshores of Belfast Lough. The

problems arose from the contamination by sewage of the waters of the Belfast port. In 1908 the Belfast Health Commission reported on the high incidence of typhoid fever which had prevailed for many years, and the nuisance of offensive smells from decomposing seaweed on the foreshores. The growth of the seaweed (*Ulva latissima*) in the polluted water was encouraged by the free ammonia content of the sewage effluent.

The high incidence of typhoid fever was attributed to the consumption of sewage polluted shellfish gathered from the foreshores. It was probable that the sewage derived its specific infection from the large number of carriers. These problems were ultimately solved by the provision of a proper system of sewage disposal.

Health Control at an Air Port

Dr W. G. Swann referred to the fact that the Public Health Aircraft Regulations, 1938, made under the Public Health Act 1936 were not applicable to Northern Ireland. These regulations had been designed to conform with the International Sanitary Convention for Aerial Navigation, 1933. There had since been a further convention, in 1944, and it was likely that the existing regulations would be modified at an early date to conform with the new recommendations.

Dr Swann summarized the methods of sanitary control of infected aircraft and aircraft from infected areas. The procedure included the medical inspection of passengers and crew, isolation of infectious cases, quarantine and surveillance of contacts, and the disinfection and disinfestation of articles and aircraft. He also listed the aerodromes recognized under the International Sanitary Convention.

There had been some changes in procedure in connexion with the arrival of aircraft from yellow fever areas in countries where the conditions might be favourable to its dissemination. These included the compulsory disinfection of the aircraft and for passengers failing the possession of a valid anti-yellow-fever international certificate, isolation in screened quarters over the incubation period. As a safeguard against smallpox the Convention permitted isolation for a period up to fourteen days where the medical officer indicated that there was a grave risk of infection.

In the course of the meeting members were entertained by the City Council of Belfast and by the Government for Northern Ireland, and they also visited many places of interest.

Reports of Societies

HOMOSEXUALITY

A joint meeting of the Medico-Legal Society and the Section of Psychiatry of the Royal Society of Medicine was held on April 8 for a discussion on the social problem of homosexuality. Prof. AUBREY LEWIS presided.

Dr E. A. BENNET said that among homosexuals there was every variety of character. The attitude of homosexuals towards their inversion varied; many of them regretted their exclusion from normal family life. Doctors and lawyers tended to think of homosexuals as unstable, but it was unwise to generalize and it was doubtful whether social instability was commoner among them than among others. The number of persons found guilty of homosexual crime was of course, only a small proportion of the homosexual population. The number of homosexuals in this country was not known. Havelock Ellis had mentioned 2%, similar to the proportion of inverts in other lands, and this would account for nearly a million. A fact-finding investigation was badly needed. The social problem of homosexuality was of such importance that a representative committee should be set up immediately to accumulate information concerning the number of homosexuals, the significance of constitutional and hereditary factors, the effect of environment and the results of psychiatric treatment. Those who had to form programmes of sex education would be helped by such a fact-finding survey. There was no accepted criterion of homosexuality; it had many forms and degrees. Nor was there any acknowledged standard of treatment. In women homosexuality was probably as common as among men, but

it was less prominent, received less attention, and was not affected by the social and legal strictures which compelled discretion in the other sex. He also referred to the loneliness of the homosexual, who was compelled to seek the society of others like himself or to live in emotional isolation.

Moral Indignation

Dr H. MANNHEIM said that society should treat as crime only such behaviour as was distinctly antisocial—that is to say harmful to the community at large. A strong feeling of indignation was not enough to justify judicial action. Many types of behaviour in political, religious, and other spheres aroused public indignation but were not treated as crimes. From Henry VIII until 1763 homosexuality came under ecclesiastical law, and was regarded as identical with heresy, which might explain much of the moral indignation and consequent stigma it occasioned. It had been suggested by medical psychologists that in certain cases a cure could not be effected without an element of public condemnation and repression. There might be cases of that kind, but the speaker doubted whether successful treatment was in itself a justification for a sentence of imprisonment, cure might be bought at too high a price. His conclusion was that homosexual activities should be punished as crimes only if they tended to corrupt young persons or were carried out for gain—as, for example, male prostitution. In his view the criminal law should not be extended beyond that. He also discussed the effect of prison or institutional life upon homosexual tendencies. It was a question whether it might not be possible to reduce the rigidity of sex segregation among young people in institutions and so reduce the incidence of homosexuality. Further research was needed, and the experience of other countries should be studied.

Classification

Mr D. STANLEY-JONES spoke of the need for revising the classification of the condition. Of the congenital or intrinsic type of homosexuality little was known, although certain theories had been advanced in tentative explanation. Physiological homosexuality indicated an individual predisposition, and was rarely amenable to successful psychological treatment. Continental workers had shifted from the view that homosexuality was a process towards degeneration, many now thought it to be a variation, a simple anomaly. The question of moral and legal responsibility could not be evaded by simple disclaimer. A distinction might be drawn between uncontrollable impulses and impulses which could be held in check. The only plea which was recognized as giving sanctuary was insanity and this could not be applied to the homosexual. But the problem of reconciling the terms of the law with the present rights of the abnormal but not vicious individual was not so difficult as it might appear. Leaving aside the private relations of homosexuals one with another, the only offence, other than blatant importuning, which could come within the law was the seduction of young persons, and this particular type of offence was rarely committed by the natural invert, whose affections almost invariably went out to an adult of his own sex. A fully developed homosexual who had reached psychological maturity would no more think of seducing a small boy than would a normal heterosexual. The seduction of children bore no direct relation to homosexuality as such, but was evidence of a departure from normality or a failure to reach maturity. The homosexual had a just claim to be treated in this respect on a parity with the heterosexual.

Acquired, functional, or psychological homosexuality, as it was variously described, fell into a different category. By far the greater number of wrongdoers were not natural inverts but immature heterosexuals or bisexuals, and the reasonable claim of bona-fide inverts to a just recognition of their rights as a social minority was prejudiced by the actions of others. In contradistinction to the intrinsic type, in the acquired type of homosexual psychotherapeutic measures usually met with success, leading often to complete cure.

Female Homosexuals

Dr W. NORWOOD EAST, president of the Medico-Legal Society, said that it was misleading to consider homosexuality as being similar in the two sexes. He could not

recall any woman homosexual who had committed murder or had been murdered because she was homosexual but cases of that kind had occurred among men. It was a further fallacy to suggest that because homosexuality in women was not penalized homosexual offences by men should escape penalty. Women lawyers and doctors coming in contact with female homosexuality were somewhat alarmed at its extent. In some cases there appeared to be a specific inherited tendency. It had been found in males that the most important environmental factor was early seduction by homosexual men, other environmental factors were difficulties in ordinary sexual life, venereal disease and severe emotional disturbance. There was no reason to believe that the homosexual urge was stronger than the normal sexual urge. Many confirmed homosexuals were perfectly potent in heterosexual relations.

The young male prostitute as a rule was not homosexual. He wanted an exciting life or money without the trouble of earning it. The young adolescent male gave up prostitution more easily than the young adolescent female, not because he was more moral, but because the female carried her fantasy further on into life. If the homosexual could be prevented from menacing public security and be relieved by medical or social aid he need not be sent to prison, but there were cases in which such a course was too risky and in these imprisonment might be advantageous. Favourable conditions were youth, a good personality, a first offence, no homosexual habit, a genuine anxiety to overcome the tendency co-operation with the psychiatrist, and good health. The time was far distant when penalties for homosexual offences could be abolished and if the homosexual debauched a young child, or offended against public decency, or carried out his activities for gain or accosted other persons, it was right that he should be penalized.

Prison Experience

Dr J C MACKWOOD said that some individuals who had broken off treatment outside prison had done well during a subsequent prison experience. The value of psychotherapy in prison was quite definite. Much of the machinery of prison life was out of date, but during the four years for which he had been doing this work he had seen a number of improvements take place inside prison. One of the greatest handicaps was lack of space in prison for the expression of healthy energy; another was the long hours of isolation for individuals whose main trouble was that they were already isolated personalities. Signs of improvement were alteration in individual bearing and demeanour, acceptance of ordinary prison regime, improvement in relationships between individuals and great liberation of energy. Follow up after prison was difficult, the more so because the prisoner wanted his prison life to be a closed book. Dr ALBERTINE WINNER said that it should be realized that the average lesbian did not regard her condition as abnormal at all or different from that of other people, only in a small proportion of cases was she promiscuous. Dr STAFFORD CLARKE said that the question of punishment depended on whether homosexual activity was criminal in the sense that it interfered with other individuals.

Dr CLIFFORD ALLEN said that the correct view to take of homosexuality was that it shaded off into heterosexuality, there was no clear cut division. In his experience homosexuality was mixed up with other perversions. Prison was the worst possible place in which to treat homosexuality. Segregation from the opposite sex encouraged the condition. Psychotherapy would produce good results in a patient who wanted to be cured. In Germany homosexuals were castrated. In America leptazol was used as a form of therapy; he had also seen a number of cases which had received electrical treatment, but they had been failures.

RHEUMATIC DISEASES

SAMUEL HYDE MEMORIAL LECTURE

The Samuel Hyde Memorial Lecture was delivered to the Section of Physical Medicine of the Royal Society of Medicine on April 9 by Prof HENRY COHEN.

Prof Cohen began by referring to recent surveys which showed that one-sixth of the total industrial invalidism in

England and Wales was ascribed to rheumatic diseases. From a United States survey it appeared that over 5% of the total population suffered from some form of rheumatism. These surveys furnished only a general impression of the prevalence of the disease but all of them suggested its great extent. In rheumatic diseases the greatest care was needed not only in interpreting the results but in planning large scale surveys and the closest co-operation between statistician and clinician was required.

Nomenclature

The question of nomenclature also must be clarified. "Rheumatism" and "gout" had sufficiently strong historical roots to survive outmoded pathology, but many names given to the group of rheumatic diseases failed to describe them properly. He suggested that the names should be associated with the anatomical sites of the disease, even though this might bring in conditions not usually associated with rheumatism. Rheumatic fever had a distinctive feature in cardiac involvement, even though the aetiology was obscure, but such terms as fibrositis, neuritis, strains, and adhesions were often the refuge of the diagnostically destitute.

The gap between the incidence of rheumatic diseases and facilities for treatment Prof Cohen continued would take years to bridge. The reason for the neglect of rheumatic diseases in the past had been, in the first place, that rheumatism was not a fatal disease. It ranked fourteenth in the causes of death, and it lacked the dramatic appeal of cancer, tuberculosis, and heart disease—an appeal which attracted the philanthropic. Yet the Government could view with unconcern one of the major causes of industrial invalidism. Again, the treatment was less spectacular and less overtly rewarding than in other diseases, even the best results often left the patients with fundamental disabilities and deformities. There had also been a lack of co-operation between physicians, orthopaedic surgeons, physiotherapists and others whose team work was necessary if maximum recovery was to be secured. Neglect by the competent had left the field too widely open to the incompetent. Sufferers had succumbed to the blandishments of the unorthodox, and the law had permitted the sale of nostrums, which maintained their reputation because the natural remissions obtaining in most rheumatic states were attributed to their use.

In the students' curriculum no adequate place had been given to the study of rheumatic disorders. The student might be able to diagnose many advanced types correctly, but his knowledge of early cases and of the various forms of arthritis, the possibilities of treatment, and the value of orthopaedic measures of occupational therapy, and of rehabilitation was apt to be far from adequate.

Four Directions for Action

These considerations called for (1) research, (2) planning of a comprehensive service, (3) greater interest on the part of the medical student and practitioner in the scope and diagnosis of rheumatic diseases and (4) opportunities for those who wish to specialize in this field. Research closely associated with medical schools and hospitals should cover all aspects of rheumatism—in the laboratory, the field, and the clinic. The incidence of rheumatism in miners, dockers, and postmen, for example, should be studied. In the case of the miner, what were the effects of humidity in mines, of posture of deprivation of sunlight, and of faulty housing? The influence of hours of work, of psychological factors, of rest periods in relation to prophylaxis should be investigated. Many fundamental problems needed elucidation, and new problems continually presented themselves with discoveries in other fields. More basic investigation into the mode of action and effects of the methods employed in physical medicine was called for.

Hospital beds in which patients could remain if need be for months and clinics where minor forms of rheumatism could be treated and ex-hospital patients continue to receive attention, were needed. Diagnostic and research centres should be set up in the teaching and the larger general hospitals each of them linked with out-patient clinics and providing short stay beds for investigation.

The challenge Prof Cohen concluded lay in the incidence of rheumatic disease, the present inadequate understanding of

varicose veins

the most efficient injection treatment

Ethamolin offers specific advantages over any other sclerosing agent for varicose veins. Given sufficiently early Ethamolin frequently brings lasting benefit, marked relief can be obtained even in cases of prolonged untreated varicosity. Ethamolin forms a firm, adherent thrombus. Sloughing is not caused if the solution escapes around the vein and there are no general reactions except in the very rare case of hypersensitivity. The total dosage required is normally less than 6 cc., being powerfully bactericidal. Ethamolin reduces the risk of infection to a minimum. With Ethamolin the practitioner is thus equipped to deal with the majority of his varicose patients without need to resort to operative measures.

it and the basic neglect. The opportunity which this challenge presented came with the introduction of the National Health Service, which promised to every citizen the treatment he needed, but the opportunity was also a heavy responsibility for medicine. Even with present knowledge, if there were sufficient hospital beds and adequate treatment facilities the invalidism resulting from rheumatism could be greatly lessened.

Correspondence

International System of Weights and Measures

SIR—In his letter (May 3, p. 613) Dr D. A. K. Black is presumably referring to the method of recording volume in results obtained from the haemocytometer. As the haemocytometer is calibrated in linear measurements the volume is derived from these measurements and should be expressed in terms of the cube of the unit of linear measure—in this case the cubic millimetre. I pointed out in my article that the cube of a linear measure is a valid mode of expressing volume when the volume has been determined from linear measurements.

Mr H. V. Stopes-Roe in his letter (p. 613) is correct in expressing volume as a cube of linear measurement if the volume has been actually determined from linear measurements, but it should be made quite clear that such is the case—that, for instance, the cubic centimetre which he uses is actually a cube centimetre and is not used as an alternative to the millilitre. Although the expression of volume as a cube of linear measure is a valid procedure when it has been determined from linear measurements it is not nearly so simple to determine the volume of a container from linear measurements as it is to determine the weight of water required to fill it. Consequently units of volume came into existence defined in terms of the space occupied by a definite mass of water under specified conditions. The litre is the space occupied by a kilogram of water at its maximum density. This definition has the additional advantage that the kilogram, litre and millilitre are interrelated whereas the cubic decimetre and cubic centimetre are not related to the kilogram.

There is some obscurity in the following sentences from Mr Stopes-Roe's letter: "It is a purely legal form (like the gallon) that the millilitre got started—scientists writing scientific articles should refer to the cm³ unless they are actually and significantly using the millilitre. If they be writing legal reports they should use throughout whatever odd units—yard, drachm, or litre—that may be legally required." If I understand Mr Stopes-Roe correctly I agree that scientists should use the term "millilitre" when they are "actually and significantly" using the millilitre, on the other hand, they should use the term "cubic centimetre" only when they mean volume derived from linear measurement. Both these modes of measurement have scientific validity when used strictly in accordance with their definitions; they are also both legal measures when used in their proper meaning.

As regards publication surely the description of units of measurement should depend upon the units actually used and not upon whether the publication wishes to be scientific or legal.—I am, etc.

J. M. HAMILL

Tuberculous Pericarditis

SIR—We read with interest Dr Harry Kopelman's article on tuberculous pericarditis (April 26, p. 559). Of over 1,400 consecutive cases admitted to the pleural effusion unit of this hospital since 1942 six were complicated by pericarditis—an incidence of less than 0.5%. The diagnosis of tuberculosis was proved bacteriologically in three cases, and was made on strong presumptive clinical grounds in the remaining three. Three patients were males and three females. There were three deaths and two recoveries; one patient still being in the acute stage of the disease. The following is a brief summary of the case histories.

Case 1—A man aged 24 years, of Irish descent, was transferred to this hospital convalescent from a left pleural effusion and suffer-

ing from a serous pericarditis, in May, 1942. Tubercle bacilli were grown from the pericardial fluid. He made an uninterrupted recovery, and was discharged in October of the same year. Two years later he was known to be alive and well.

Case 2—A man aged 22 years was transferred to this hospital from Bath in April, 1944, suffering a right pleural effusion complicated by a gross pericardial effusion. He had signs and symptoms of severe circulatory embarrassment. He was tapped repeatedly, with air replacement. Viable tubercle bacilli were repeatedly obtained from the pericardial fluid in spite of intrapericardial injections of "promamide." He was transferred to a sanatorium in August, 1944, and died there two months later.

Case 3—A man aged 22 years, of Italian descent, was transferred to this hospital in June, 1943, suffering from a sterile lymphocytic pleural effusion on the right side. He relapsed in January, 1944, developing a pericarditis with loud friction sounds and little alteration of the cardiac shadow. He made an uneventful recovery and was discharged in June, 1944. Six months later he was re-examined, and, apart from some slight pleural thickening on the right side, was found to be well.

Case 4—A girl aged 16 years was transferred to this hospital in April, 1943, with a sterile lymphocytic effusion on the right side. There was a strong family history of tuberculosis. Her effusion cleared, but in July, 1943, she developed an acute pericarditis with effusion. Paracentesis was twice performed to relieve distress, pale greenish fluid being obtained which was sterile on culture. She deteriorated rapidly and died on July 31, 1943. Permission for post mortem examination was not granted.

Case 5—A married woman aged 23 years developed a pleural effusion on the left side following the birth of her first baby in February, 1944. She was transferred here in March, 1944. On admission she was still febrile, and was acutely ill. In the middle of April she developed an acute pericardial effusion. A paracentesis showed a serous fluid, from which tubercle bacilli were grown. She deteriorated rapidly and died on May 12, 1944. Permission for necropsy was not granted.

Case 6—An unmarried woman of 25 years was admitted to this hospital in February, 1947, suffering from a right pleural effusion. She was still pyrexial on admission. Eight weeks after her admission she developed precordial pain and a sensation of constriction in the chest. A loud and definite pericardial friction rub then appeared and has persisted since. There is no evidence of a pericardial effusion of a significant size. She is still in the acute stage of the disease.

Tuberculous pericarditis is thus seen to be an uncommon but not rare complication of tuberculous pleural effusion, and to be a disease with a variable course and prognosis, though the latter is grave.

We would like to thank Dr Clifford Ellingworth, medical superintendent of Queen Mary's Hospital, Sidcup, for permission to publish these case reports.

E. MONTUSCHI
T. L. REEVES

Tuberculosis and the NHS Act

SIR—I much appreciate the views expressed by Dr G. Lissant Cox (April 26, p. 577) regarding tuberculosis and the NHS Act. These are the opinions of a distinguished tuberculosis worker "in the field" who has recently earned a well deserved retirement.

As one who has had an experience of over thirty years in this centre, directing measures for the control and elimination of tuberculosis and who for the six war years assisted a powerful medical officer of health in his department, I foresee the grave danger of a cleavage between the hospital service, particularly as regards tuberculosis and mental welfare, and general infectious diseases, and the local authority—the domiciliary service. This cleavage might be obviated by building three bridges—at the centre, at the region, and at the hospital group levels.

At the centre by appointing three committees: (a) For tuberculosis, (b) for mental health, and (c) for infectious diseases. Similar committees at the regional and hospital group levels. Other committees to be formed at the three levels for maternity and child welfare and any other services requiring unification for their successful operation. Each committee to be composed of persons specially interested in that particular subject and guided and advised by "specialists" in that particular subject.

The health visitors of the local authority to act as investigators in the homes along with the sanitary inspectors, and specialized health visitors to be attached to the various medical nursing and clerical teams operating at the hospital group and local authority levels.

Taking the tuberculosis service as an example. The primary notification of tuberculosis would be visited by the health visitor who would report on the housing conditions and general sociological circumstances. The primary notification would by law be sent to the local medical officer of health as chief epidemiologist who would delegate the subsequent measures to the senior tuberculosis officer of the hospital team, the subsequent visits to be carried out by the 'specialized' health visitors who attend the various clinics and are kept informed of everything affecting the patient and his family, the senior medical officer of the team to work in close harmony with the medical officer of health, particularly as regards housing and other necessary conditions. So far as after care is concerned this should be in the hands of the committee at the hospital group-local authority level and advised not only by the senior medical officer but also by the medical officer of health.

The framework could be extended to meet the needs of all other services, but modified according to the special needs of this service. Once the framework is accepted, the details can easily be filled in provided there is good will and a wide understanding—I am, etc.,

Bradford

HAROLD VALLOW

SIR—There are two facts apposite to the impending changes in the tuberculosis service which have so far received scant recognition. The first is that the relationship of the patient to his domestic, social, and economic background, which is now receiving so much attention and which to general medicine is a relatively new conception, has in fact been the everyday concern of the tuberculosis officer for many years. Secondly, the anti tuberculosis organization as it has developed since 1914 has given us the nearest approach we have known to a public medical service providing hospital, clinic, and domiciliary treatment at a high clinical level for sick persons in large numbers. Despite certain inherent weaknesses and inequalities, and despite in some quarters official apathy and parsimony it has emerged with a record of which it may well be proud.

For these two reasons the views of tuberculosis workers claim the special attention of those who will formulate the new regional schemes. It is to be hoped that the well timed suggestions put forward by Dr Lissant Cox (April 26, p 577) will stimulate a lively discussion prior to the Minister of Health's address in July. Dr Lissant Cox rightly stresses the need for medical teamwork. This can only be obtained where all concerned are responsible to the same employer. If only one person—for instance the health visitor—owes allegiance to a different authority from that of the tuberculosis officer, almoner and clerk there is a sense of divided loyalties and the team spirit suffers accordingly.

Each tuberculosis area within a region will require a head quarters with office accommodation. It will be years before new establishments are available, and until then I suggest that in some areas the smaller institutions could with minor alterations or extensions, be adapted for this purpose. Beds would continue to be available as before and in those institutions where x-ray facilities are already provided out patient clinics could be held as in country districts, this would be an added convenience for patients. In this way the institution would become a strongly defined centre clinical and administrative for the area—I am, etc.

Chichester

J E WALLACE

Sanitary Control of Ice-cream

SIR—May I draw your attention to an inaccuracy in the epidemiological note (April 26, p 583) on the above subject? The maintenance of a sufficiently low temperature after freezing and until sale is required in the case of a cold mix product as in the case of a pasteurized mix. Circular 69/47, which was issued with the regulations points out in respect of the complete cold mix that after conversion of the reconstituted product into ice cream Regulation 4 shall apply.

This regulation forbids the sale or offer for sale unless of two conditions is met. One requiring further heat treatment should the temperature of the ice cream be found to be above 28 °F (−2.2 °C) cannot obviously apply to the complete cold mix product, the other stipulates that ice cream shall be sold unless it has been kept at a temperature not exceeding 28 °F since it was frozen.

I should be grateful if you would draw the attention of your readers to this rather important aspect of ice cream control. I am, etc.,

Massive Penicillin Doses

SIR—Dr D P Wheatley (April 19 p 530) has shown that the daily parenteral administration of penicillin can accelerate the resolution of localized septic foci if the doses are large enough. Thus, for the treatment of what he calls 'several cases of minor conditions commonly met with in general practice' he used 4,550,000 units of penicillin. The total period of convalescence from the commencement of treatment was at least 30 days.

From the few cases that I have treated I have been under the impression that a more rapid cure can be achieved by the combined use of local penicillin and free surgical drainage. The solution recommended for local use by Roxburgh contains between 500 and 1,000 units per ml of distilled water and gives satisfactory results. In one case a pyogenic abscess of the days' duration was opened by a 1-in (2.54 cm) incision, as a cavity 1/2 in (1.25 cm) in diameter was found. A drain was inserted and penicillin was instilled. Twelve hours later the discharge was slight, and the drain was removed. On the fourth day, after daily instillations of the penicillin solution, the cavity was obliterated and the skin incision was clean and dry and healing rapidly. (Total amount of penicillin used was 4,000 units.)

If as Dr Wheatley has noted, the systemic treatment with penicillin is commenced early enough, the inflammation will abort. But, in cases where there is some delay in starting treatment, the generalized symptoms of toxæmia and the signs of inflammation will subside leaving a localized collection of pus which requires surgical treatment. It is suggested that once it is decided that the inflammation is progressing to abscess formation but before localization is complete, the area should be incised to relieve the local tension and pain. The level of penicillin in the blood stream will prevent a spread of infection through the channels opened up by the incision. Then after the systemic penicillin may be discontinued as soon as the general condition of the patient merits it—usually three injections of 30,000 units each is the total amount of penicillin required. The local treatment is continued daily until the purulent discharge ceases, when the further treatment is the same as for a clean surgical wound. Such a procedure however, could only be justified if the organism is sensitive to penicillin. This can be assessed by the progressive localization of the inflammation under the systemic treatment.

In this way greater economy in the use of penicillin can be achieved, the discomfort of repeated intramuscular injection is reduced, and the patient's convalescence is shortened. In addition it is suggested that a stronger scar and a better cosmetic result is achieved because the tension of the abscess is relieved before the overlying skin has become stretched and atrophic—I am, etc.,

Penicillin Its Practical Application (Dermatological Section). Edited by S Alexander Fleming. London: Butterworth and Co. 1946.

Rubella in Pregnancy and Congenital Defects

SIR—Because of the interest taken in this association this single case may be worth publishing. It was the mother's first pregnancy and resulted in a normal full term delivery, birth weight, 5 lb 9 oz (2.5 kg). The boy was born on Jan 14 1947 and was seen for the first time a month later at an infant welfare centre in South London, when his mother was having considerable difficulty in getting him to suck satisfactorily. He was found to have bilateral cataracts and a loud systolic murmur heard over the whole left chest, he was never cyanosed. He

reacts sluggishly and appears to be deaf. He has progressed slowly and is now, at the end of April, 8 lb 10 oz (3.88 kg).

The father is 29 and healthy. His sister had rheumatic carditis at the age of 14 and his father had a "displaced heart," which never made him ill. The mother is 22 and robust. On inquiring about her health during the pregnancy she said that she was very well except that she "caught German measles from her sister during the first month." The attack had apparently been mild and had not made her feel at all unwell. The Wassermann reaction, taken at the antenatal clinic, was negative. Her sister and the other members of her family, father and mother, are all well—I am, etc.,

Treatment of Post-operative Pulmonary Atelectasis

SIR—In an effort to prove that his pen is mightier than the spear, Mr R. C. Brock in his letter (April 19, p. 543), out-Quixotes Quixote by tilting at illusory windmills. Indeed, all must agree with practically everything he says, but the tone of his letter requires that I should explain myself in rather more detail.

In saying that bronchoscopic aspiration is the ideal method of treating post-operative atelectasis I of course meant that it was the most effective (as Mr Brock himself admits), not that it had no imperfections, nor must he condemn me as ignorant of the well-known benefits of prophylaxis and of conservative methods of treatment simply because, in describing one particular manoeuvre (this word suggests less of charlatanism than "trick") these benefits were not stressed, nor, of course, is it material to that manoeuvre whether water be introduced into the trachea by injection through the windpipe or by instillation through the glottis, so long as coughing results. Incidentally, injection is not so unpleasant as it sounds, and there is little to choose between the two methods.

On all the above points Mr Brock and I are in agreement. Where we really differ is on his statement that the objections to bronchoscopic aspiration are, first, that it encourages laziness, which might more reasonably be used as an argument against penicillin or the sulphonamides; and, secondly, that bronchoscopy is dangerous in unskilled hands. This latter may be true, but it is no more an argument against bronchoscopy than it is against appendicectomy; on the contrary, it is an extremely good reason why anaesthetists should become, as I said in my last letter, experts in bronchoscopic aspiration and in thoracic disease—I am, etc.,

Newcastle-upon-Tyne

M. H. ARMSTRONG DAVISON

Treatment of Ingrowing Toenail

SIR—I was very interested to read the remarks by Dr S. J. D. Esser (Jan 4, p. 33) on the above subject, and entirely agree with him. I have performed a similar operation on over fifty patients, only one of which was temporarily unsatisfactory. The patient, a very conscientious engineer officer, would not remain in bed but got about immediately, with the result that convalescence was delayed. Some of my more athletic patients played football a month after the operation with no ill effects.

I first came across a description of the operation in question some years ago in a French medical journal; the writer was a French surgeon. Unfortunately at this date I cannot recall his name. In his description a diamond-shaped portion of the soft tissue is removed, the knife cutting down to the bone, three catgut sutures are inserted—the end ones being tied first, the middle one last—and there should be little or no tension. Performed in this way the final result is a linear scar, the overlying soft tissues being drawn well away from the lateral margin of the nail. He emphasized the importance of a thorough preparation of the foot prior to operation and insisted on complete rest afterwards until removal of the sutures. This, although rather irksome to the patient, is essential if a good result is to be obtained.

Following these instructions I have never had to perform a second operation for the relief of this condition. As Dr Esser says, there is no doubt about the operation being simple, logical and effective, and I congratulate him on bringing it to the notice of the profession—I am, etc.,

Surgeon-Commander R.A.N. (Retd.)

Safety in Electric Convulsion Therapy

SIR—I have read the letter by Dr R. A. Sandison (April 26, p. 579), and I am very gratified by such common-sense thought. His experience is entirely in accord with my own over seven years' experience of electric convulsion therapy. I have treated a large number of cases both as in- and out-patients by this method in the last two years without traumatic occurrence, and between 1940 and 1945 had only three cases which showed evidence of compression of one vertebra after x-ray examination. I came to the conclusion that this compression was more a radiological disease than a pathological one, and I have not seen any disability resulting from it.

I always use a firm surface with a pillow placed under the thoracic spine and no other mechanical restraint. It is, therefore, in my opinion quite unnecessary to use curare. As far as lessening the apprehension by means of thiopentone, as Dr Sandison says, patients are not afraid of the treatment but sometimes are upset by the amnesia and confusion, which as a rule are only transient, and again are very readily relieved by a chat with the patient following treatment, or by warning the patient before that such symptoms may arise for a short time. No advantage, therefore, in my opinion can be obtained by the use of curare or thiopentone apart from the very dangerous results which may follow its use.

Again let me congratulate Dr Sandison—I am, etc.,

J. P. MCGUINNESS

The Shortage of Nurses

SIR—The purpose of this letter is twofold: first, to bring to the notice of the medical profession a very real danger to the future supply of nurses; and, secondly, to ask whether the theoretical training of the modern nurse has not reached the stage when it is endangering the practice of nursing.

It seems to me that the following decision of the General Nursing Council has not received sufficient attention in the medical press—namely that as from May 31, 1937, no hospital with less than an average of 100 occupied beds per day will be recognized as a complete training school. By this decision the General Nursing Council would appear to be following the present-day trend of the pursuit of ideologies without regard to the practical issues involved. The law of economics is one of demand and supply; if the supply is inadequate and further demands are put upon it the result must be chaos.

The smaller hospitals throughout this country have for many years supplied a large number of trained nurses. They have instructed and individually spoon-fed girls who, from lack of primary education, would have failed to stay the course in the larger hospitals and have turned them into reliable nurses. In the future these smaller hospitals can never be staffed by senior nurses, and they will have great difficulty in attracting junior nurses who will prefer to enter the complete training schools.

It is generally acknowledged that the standard of education of the present-day nursing recruit is not as high as it was ten years ago. Yet with insufficient grounding the nurse of to-day is expected to have a knowledge of medicine, surgery, gynaecology, and many other subsidiary subjects that would not disgrace the average medical student. Of what practical use is the nurse full of theory who cannot make her patient comfortable, and, who, for example, though she can quote correctly the precise figures of the normal blood urea, yet is unable to see that her patient is in the early stages of renal failure by his drowsiness, his breath, his tongue, and his diminished output of urine? The nurse should have sufficient textbook knowledge to enable her to take an intelligent interest in her work. She should be trained not to the theory of medicine but to the art of nursing; the class room can never replace the ward. In my opinion it will be cold comfort for the patient when a graduate nurse does his dressing, a student nurse gives him an enema, an assistant nurse washes him, and an orderly looks after his meals with a complete change of personnel for every eight-hour shift. Not one of them will look upon him as her individual responsibility, and the faith of the patient will be correspondingly lessened.

It is admitted that the smaller hospital is no longer an economic unit, and that the larger one of 400 to 500 beds is the hospital of the future. At the present rate of building it may well be twenty years before the latter comes into existence.

With the new Health Act the demand for nurses is going to increase. Rightly the General Nursing Council has the ear of the Government. Does a similar liaison exist between the General Nursing Council and the medical staffs of hospitals who are interested in the supply of nurses—through for example the British Hospitals Association? Is this the opportune moment for the General Nursing Council to enforce its decision?—I am, etc.,

Ashford Kent

JOHN C HODGSON

Cement Dust

SIR—Under the heading "Any Questions?" (April 12 p 515) your correspondent in reply to an inquiry about cement dust being injurious to health or not, states that research into the matter has revealed no gross lesion of the lung tissues from the prolonged inhalation of cement dust among those engaged in its production. He says, however that it may cause irritation of the conjunctiva, skin, the nasal and upper air passages the latter including I suppose, the trachea and large bronchi, presumably resulting in conjunctivitis, dermatitis nasopharyngeal catarrh tracheitis and bronchial catarrh. Personally I have no doubt about its being able to give rise to those complaints. Such being the case one must conclude that, although not seriously injurious to health it does not contribute to the maintenance of health to the extent one would like to enjoy it if the air one is forced to breathe night and day were free of cement dust pollution.

It is a well known fact that in Germany no dust comes out of the factory chimneys. Obviously it is because methods of preventing the emission of dust are made use of. Could not such measures be employed in England for the same purpose, involving as they might highly technical and engineering questions? It is only a matter of expense and of enlisting the services of people who are capable of solving in a practical manner those questions, as it is done in Germany.

Your correspondent obviously does not have to live in districts where air pollution by cement dust prevails. Even if he happened to reside in these districts and were content to make the best of things in the belief that his health would not suffer seriously I feel sure he would very soon realize the very grievous nuisance a cement-laden air can be and would gladly join in the request that it may be removed.

The Minister of Health in reply to a letter of mine, once said that cement dust was not *seriously* injurious to health. Nothing that can be prevented should be allowed to exist even if its effects on health are comparatively slight. If on that account the matter does not come within the purview of the Ministry of Health it is certainly of such a nature as to call for intervention by the Ministry of Nuisances if such a Department exists in England, as it apparently does in Germany.—I am, etc.,

Greenhithe Kent

D W STANDLEY

Child Guidance

SIR,—It is interesting to note that Drs J A McCluskie (April 12, p 508) and S Sharman (April 26, p 580) both agree as to the desirability of the psychiatrist to a child guidance clinic having previous experience in general practice. The authorities seeking such psychiatrists however, almost without exception demand the D P M, or equivalent qualification which to all intents and purposes means experience of work in a mental hospital.

The latter experience is I should have thought almost totally irrelevant to child guidance work, since, as Dr McCluskie suggests the large majority of cases coming before a child psychiatrist do not involve any diagnosis or treatment of *mental disease*. They do however always present psychological problems—social educational and personal. This is an entirely different matter and demands not experience in the diagnosis and treatment of psychosis but profound knowledge of the dynamics of emotional development from infancy onwards and of the forces which may damage or arrest it and ability to apply this knowledge sympathetically and realistically.

It is the last word which points to the need for experience in general practice an experience unique in giving the doctor entrance to the homes in which children are born and grow up. The psychiatric social worker has this entrance but only in connexion with the immediate child guidance problem, and valuable as are her 'social histories', they will be responded

to far more usefully by the man or woman who is familiar with the types of home and situation presented than they can be by a specialist whose experience has been gained in institutions and/or consulting room—I am, etc.,

Peppard Oxon

LAURA HUTTON

Tobacco

SIR—If the increased cost of tobacco were really to result in a marked reduction in consumption over a number of years then the question whether we are really a nation of oral eroticists would be well on the way to a solution—or would it? The dentists don't seem to have any vital information to give us about the nation's teeth after 7½ years of enforced reduction in the consumption of sweets and sugar.

Of course there is more to smoking than just sucking. Perhaps the doing without might result in an increased national intelligence instead of the seemingly inescapable decline which may or may not have had some connexion with smoking. Or will some other mild vice happen along to take the place of tobacco? It is interesting to speculate what this might be save the obvious vices of sweet-sucking and tipping, both of which are at present out of the question. Perhaps potency will be stimulated and the gloomy portents of a shrinking population refuted?

Again—always provided there is a real reduction, and spread over a long enough time, which I doubt—apart from minor physical changes such as increased appetite with little to appease it and slight improvement in vision and wind my own view is that such a real abstinence with nothing to take its place would result in a very definite restlessness, increased energy, particularly mental energy intolerance (inability to bear fools gladly), and a dangerous boredom. How I wish it would happen!—I am, etc.,

Thame Oxon

E GRANGER

SIR—We pay lip service to preventive medicine. Vast sums of money are to be poured out on the altar of national health yet all we can do about the tobacco tax is to crave "relief" for invalids, pensioners, etc.

Look again, Sir, with open eyes at the grown man still sucking his pipe, at the yellow-fingered female inhaling between her paroxysms of cough great gouts of acrid smoke into the ramifications of her bronchial tree, peer through the billowing smoke of the theatre auditorium at the serried ranks of smouldering addicts squashing their stubs into carpet or tray fiddling with lighters, probing their pipes, and cough coughing. And then maintain if you can, that the tobacco habit as practised to day is anything better than a melancholy commentary on *Homo sapiens*—I am, etc.,

Uckfield Sussex

W R E HARRISON

Occupied Holland

SIR—The final paragraph of the article on occupied Holland by Dr Henriette A Lohr (April 19 p 540) is perhaps worthy of special consideration. Dr Lohr writes "We have learned some things during this hunger period. Even those who didn't get oedema have experienced a curious change in their outlook and behaviour which varied from complacency and apathy to irritability. Formerly we may have scoffed at the poor for not being able to grasp the many opportunities which life offers to better their conditions. We never realized the fundamental significance of food."

It has been observed in a number of experiments that shortage of a variety of food factors may give rise to subclinical deficiency states marked only by lassitude or irritability. Another mental effect of prolonged rationing may perhaps be illustrated by an example. In the Western Desert during the war water was often very strictly rationed and it was a common experience for men who had been some time in the desert to feel when they came out a strong inhibition against the free use of water. This attitude might last many months, even when water was unlimited. In this country with food short, the prolonged strain of war and need for self-control so that each might have his share have I think tended to produce an almost unconscious inhibition. A subclinical state of undernutrition through rationing may be widespread and marked only by

apathy or irritation. In such a state we scarcely realize what we need nor fully appreciate what we miss, a condition which is not conducive to the great effort required for national recovery.

MARTIN HERFORD

London W 1

Reshaping the Curriculum

SIR—I read with keen interest the special article and annotation on the subject of the curriculum (May 3, pp 606 and 608) and would like to make a few observations.

Might not a course of elementary pathology be given to all students in the London hospitals prior to their entry into the wards as is done at the older universities? To arrive in the wards with a rudimentary knowledge of disease processes must be very advantageous. Would it not be wiser to arrange for pharmacology to be taught alongside medicine, as it is essentially one of the clinician's handmaids? It does seem that to observe the effects of, e.g., adrenaline or digitalis on a cat in the preclinical sphere is rather to put the cart before the horse. Is it not yet time that dietetics had its rightful place in the academic side of medicine? Few students, one feels, leave hospital with a sound knowledge of dietetic requirements. I suggest that the official hospital dietitians be enlisted to give a simple course of instruction on food values and their subsequent clinical implications. Most patients will usually, somewhat nervously, ask their medical advisers, "Doctor, what can I eat?" In these austerity days of food rations the question has about it an added note of urgency.

Further, medicine as one of the three great learned professions should be expounded from the historical standpoint. If clergymen are required to study church history, and lawyers pursue courses in legal history, why not courses in the history of medicine? How many doctors know anything of the ancient origins and thrilling developments of their distinguished art? How many students could say who were Scarpa, Vesalius, Galen, or in more recent centuries Pott, Abernethy, Paget, and even Harvey and the Hunters? Singer's *Short History of Medicine* is a fascinating volume.

Finally, could not something be done to standardize the finals as there is scarcely a month in the year when some examining body is not conducting one of its finals? One feels that there is a good deal of latent friction existing between students taking Oxford and Cambridge degrees, London degrees, and the diplomas of the Royal Colleges and Apothecaries. This straggling of the finals all over the year appears to be very disturbing from the point of view of didactic continuity. Could there not be one final examination, e.g., an M.B., B.S. (England) conducted both in London and the provinces and held twice or at most three times a year? It would be worth giving such an academic experiment a trial—I am, etc.,

Barnstead Surrey

J B GURNEY SMITH

Medical Exchange

SIR—The World Friendship Association, of 29 Portman Square London W 1 is anxious to hear from medical practitioners who are interested in the following plan: (1) To receive as a guest for fourteen days during August a medical practitioner from Denmark or Holland; (2) to visit during the month of September a medical practitioner in Denmark or Holland and stay with him as his guest for fourteen days.

The cost for Denmark from port of embarkation to destination and return to port of embarkation will be 15 guineas. For Holland the cost will be £9 10s. An additional fee of 12s 6d for membership of the World Friendship Association is payable.

The visits will normally be direct exchanges and are contingent upon hospitalists being afforded here. The World Friendship Association is an organization which exists to foster mutual understanding by arranging mutual visits. Hitherto its visits have been available only to school-children and members of various organizations but now it is possible to extend the facilities to medical practitioners who are interested should write to G A Talbot Esq, World Friendship Association, 29 Portman Square W 1 and should mark the envelope "Medical Exchange". I am, etc.,

RICHARD W DURAND

POINTS FROM LETTERS

The Pemmican Journal

Dr J P S JAMIESON (Nelson, N.Z.) writes: I cannot forbear from writing to congratulate you and the Secretary of the B.M.A. on the issue of the *Journal* of Feb 22, 1947, which I consider the finest *B.M.J.* in my experience of nearly fifty years. It is reassuring to know that you had the permission of the Ministry of Fuel and Power and the C.O.I. to use candles and turn the handle of the duplicator. In other than a truly democratic country that might have been refused.

Marriage Guidance

Dr DAVID R MACE (London, W 1) writes: Dr Philip M Bloom (April 19, p 552) urges that more attention be given to marriage preparation as the most effective means of tackling marital disharmony by preventing it altogether. In the Marriage Guidance Council we have never been in any doubt concerning the importance of this. In season and out of season we have reiterated this theme. I hope we may claim some credit for the recent change in public opinion from definite antipathy to mild interest. But the heart of the matter lies with the medical profession. We are continually hearing from young people who have gone to their doctors for marriage preparation and been dismissed with the implied suggestion that they were wasting the time of a busy man. Until this attitude is corrected we shall make little headway towards effective preparation for marriage.

A New Outlook Needed

Dr ALBERT E NICHOLS (Shrewsbury Shropshire) writes: The medical system of this nation is in the melting-pot and the resulting conditions will decide the future of doctor and patient for many years. Those of us who are older and know the endless slavery of our past and present lives had hoped that those following us would, in common with all men, have a better life. "The patient comes first" is a noble ideal, but it is responsible for most of our troubles. Our fellow men do not care in the least if the doctor works himself to death. They can get another doctor. We have a duty to our patients and our generation, but let us not forget we have an equal duty to ourselves, our wives, children, sweet hearts, and friends. Let us revolt against this life of continuous penance and seek to secure more of the joy of living, with more time for leisure and pleasure, for it is a man's elementary right. Those of us—the majority—engaged in N.H.I. work have in addition a heavy burden quite outside the heavy responsibility of the care of human life. As a colleague put it to me, "We have always to be on guard." The slightest complaint against a doctor is most zealously investigated, while it is quite useless and a waste of valuable time to complain of a patient, who can break with impunity any rule he or she likes. We have now in power a Labour Government, put in by the workers and maintained by the Trades Union Congress. If they are consistent they will give the doctor the same consideration they would give any other worker—an eight hour day, a living wage, and a right of appeal to the law courts. It is a horrible thing that in these days of so-called human progress men should follow their profession under constant fear of fine or loss of livelihood under the regulations of a Government Department and have no protection from our law courts.

Textbooks for D.P. Doctors

Dr P J SMITH (Area Team 1069, 390 UNRRA, B.A.O.R.) writes: Excellent work is being done by our D.P. doctors in our hospitals, but they are greatly handicapped by shortage of textbooks describing the recent advances in the many branches and specialties of our profession. In Servatius Stiff Hospital, Augsburg, of which I was medical director in the latter half of 1946 are 600 beds, five x-ray plants a chemical and a pathological laboratory and all branches of medical and surgical work are encountered. The majority of the doctors can read English and would welcome used textbooks or last editions but one. I am sure many of my colleagues have on their library shelves books which though outdated by a couple of years, would nevertheless be welcomed by our doctors out here. All medical books are needed, but those on medicine and general surgery are most urgently required. However, literature on all specialties would be of service. I will gratefully acknowledge receipt of each book.

"Doctrine"

Dr A DESMOND STOKER (Winster, Derbyshire) writes: I received the following note this morning from one of my patients: "Am I practising the wrong profession?" "Dear Dr I received this bill from you and would like to know what it is about as my family and myself are all covered to receive Doctrine."

Obituary

E T WITHINGTON, M B

A few weeks ago at his residence at Oxford and in his 88th year there died on April 20 as quietly as he had lived, the best medical scholar that this country has seen since the great days of Francis Adams and W A Greenhill.

Edward Theodore Withington was born in 1860 at Culcheth Hall, Warrington, Lancs, the younger son of a country squire. As a child he seemed very frail and so remained throughout life but he was singularly free from physical disabilities. He suffered however, from a very severe stutter which made any sort of public life impossible and prevented him from being known personally beyond a small circle. Nevertheless he acquitted himself well in classics at Harrow and in science at Balliol, where he obtained the Burdett Coutts scholarship. He then spent some time at Berlin University, improving his Greek and in 1888 entered on a clinical course at St. George's Hospital, qualifying in 1891. After a short time in practice he decided to devote himself to scholarship and began a brilliant series of historical articles in the now defunct *Medical Magazine* of which he became assistant editor.

Withington early developed an admirable literary style, at once clear and allusive, always warmed by the glow of a gentle happy wit which made all that he wrote most agreeable to read. His extremely thorough work thus became much more palatable than is common with such material. He adhered scrupulously to a rule of going to his sources, in whatever language they might be, and it is thus always safe to rely on his statements. Almost everything that he wrote has some element in it of permanent value and has stood well the test of time. He married in 1897 but was early left a widower and lived for many years with his only daughter. About 1914, on the instance of Sir William Osler, he settled at Oxford, where he lived as a secluded but far from inaccessible scholar until his death. Though his intimates were few they included Sir William Osler, Dr A L Smith, Master of Balliol, Prof Stuart Jones, Prof Ramsay Wright, and Dr A G Little. The author of this notice is proud to have been admitted to this choice circle.

Withington made many admirable contributions to the history of medicine. Five of them are outstanding. First in time was his beautiful *Medical History from Earliest Times* published in 1894. Scholarship is of its nature a tree the choicest fruit of which matures late, thus such a book is a noteworthy achievement for a man of thirty-four. Nevertheless in the judgment of the writer of this notice it is within the limits of its length and the period that it treats easily the best summary of the subject in English, and he is inclined to think that it is the best in any language. Advances in knowledge in the fifty-three years that have since gone by have outdated some of its statements and generalizations but in its combination of lightness of touch, comprehensive and penetrating learning, and sane perspective the book certainly takes its place among a very select few.

Another of Withington's major contributions is his well-known essay of 1919 *The History of Greek Therapeutics and the Malaria Theory*. This careful and original account involved much research and is a model of graceful condensation of a mass of critical learning. It is, in some respects, his most characteristic work. In 1914 he edited with the late Dr A G Little an account of the works of Roger Bacon that bear on medicine. It was in the course of preparation of this publication that the author of this notice first entered Withington's circle. In 1927 Withington edited for the Loeb Library a volume of the *Surgical Treatises of the Hippocratic Collection*. There he stands out clearly as an authentic member of the great line of interpreters of medical antiquity which includes such names as Koraes, Littre, Francis Adams and Petrequin. As a scholar he is their peer; as a writer he excels them all.

Withington's most serious undertaking and that by which, in a juster world he should be longest and best remembered is his great work on Greek medical terms. On this he laboured selflessly and without thought of reward or recognition for nigh

forty years. The winnowed results of all this patient toil have been incorporated in the new edition (1940) of the great Greek lexicon known by the name of Liddell and Scott. It is the simple truth that any work of Greek medical scholarship that may appear in the future must be influenced by this modest self-effacing single minded student.

It may be that there are among the readers of this notice some who would refresh themselves with characteristic examples of the wisdom of this remarkable man. They may be recommended to the following: "John Locke as a Medical Practitioner" in *Janus* 1909, p 491; Galen, Plato and Immortality' in *Contributions to Medical and Biological Research dedicated to Sir William Osler* 1919, vol I, p 200; 'Philosophy of Galen' in the *Medical Magazine* 1904, p 8; 'Vampires in the Medical Magazine' 1896 p 1196; 'Medicine in Mediaeval Monasteries' in the *Medical Magazine* 1896 p 508 and 'The Asclepiadae and the Priests of Asclepius in volume II of Charles Singer's *Studies in the History and Method of Science* 1920 p 206. Lastly, "John Weyer and the Witch Mania" in volume I of the same work reveals that fierce hatred of cruelty and injustice that only a few of his friends knew lay behind those thoughtful gentle eyes.—C S

P R WRIGLEY, FRCS

Philip Roscoe Wrigley, honorary consulting surgeon to the Manchester Royal Infirmary, died at his home in Swettenham, near Congleton on May 2. After winning the Sam Bradley Memorial Scholarship in clinical surgery as a student of Owens College, he qualified in 1900. He was a house surgeon at the Manchester Royal Infirmary, and for two years a resident at the Pendlebury Children's Hospital. Other resident appointments he held were at Salford and at Ancoats. In 1905 he took the F.R.C.S. and returned to the Royal Infirmary as its resident surgical officer. Two years later he started in consulting practice, and was soon appointed to the surgical staff of the Infirmary, continuing in active work there until he reached the age limit of 60. During this time he lectured on operative and pathological surgery at the University and was also honorary surgeon for children at the Manchester Northern Hospital. He was at one time president of the Manchester Surgical Society and vice president of the Manchester Medical Society. In the first world war he went with other Manchester men in the 33rd General Hospital, organized by Mr A H Burgess, to Mesopotamia. He held the rank of captain, R.A.M.C., and later finished his war service under Col Westmacott at Wimereux in France.

Under average height, Philip Wrigley was an unassuming self-possessed and self-confident man doing good surgery in hospital and private practice without adding any special variations of technique of his own devising. He wrote several papers on his clinical experience of acute surgical conditions. He will be greatly missed by his former colleagues and by the many students with whom he had such friendly and cordial relations.

A colleague writes: "The death, after only a few days of illness of Philip Wrigley came as a severe blow to his Manchester colleagues. He was elected honorary assistant surgeon to the Manchester Royal Infirmary in 1910, honorary surgeon with charge of a surgical unit in 1921, and honorary consulting surgeon in 1942. For many years he was also consulting surgeon to the Buxton Cottage Hospital. He was a Fellow of the Association of Surgeons of Great Britain and Ireland and he took a great interest in the local medical societies. Wrigley made several communications to surgical literature chiefly in connexion with abdominal surgery. Small in stature "Pip" Wrigley, as he was familiarly known to his colleagues was a thoroughly efficient general surgeon, possessed of a very kindly modest and retiring disposition. He was extremely popular alike with his colleagues and his patients. Indeed, he inspired such complete confidence as to be chosen by so many of his colleagues to operate upon themselves when necessity arose that he became known as the 'surgeons surgeon'."

T N V POTTS MD

Dr Thomas Norman Vickers Potts died at Louth County Infirmary at the age of 50 on April 23 after two days illness. He was a student at Durham University and qualified M.B.B.S. in 1919. Shortly afterwards he proceeded M.D. and took the B.Hy. and D.P.H. After holding the usual residen

posts at his hospital, he was appointed medical officer of the City Infectious Diseases Hospital, Newcastle, where he remained for five years. He then became deputy medical officer of health for Birmingham. Then followed his appointment as county medical officer to the West Riding of Yorkshire in 1929 at the early age of 32. He held this office with great distinction and contributed much to the welfare of the county.

Dr Potts was always an enthusiastic member of the British Medical Association joining immediately after qualification in 1920 accepting office on the executive committee of the Wakefield Division from the commencement of his term of office as MOH to the West Riding and retaining his interest throughout. He was a most useful and business-like member, contributing fully to any matter under discussion. He was representative to the Representative Meeting in 1933 at Dublin and was chairman of the Wakefield Pontefract, and Castleford Division 1936 to 1938. He was a member of the Council of the Association from 1942 to 1944 and served on several central committees. At the 1938 annual meeting he was vice president of the section of public health and hygiene. While in Yorkshire he acted as president of the Yorkshire Branch of the Society of Medical Officers of Health, and he was a Fellow of the Royal Sanitary Institute. He had a pleasant personality and was a reliable counsellor. He leaves a widow and one daughter.

R I writes Dr T N V Potts was appointed at a very early age to one of the most envied posts in the public health service. The West Riding appointment, gained in competition against older men who were to be his subordinates, offered potential difficulties to the new CMO, but Dr Potts by a certain self-effacement and a generous attribution of merited praise to his assistants gained their unwavering loyalty and co-operation. At the time of his appointment there were many changes impending in the rearrangement of county districts, the transfer of poor law hospitals to the public health committee and the formation of a salaried midwifery service. The latter was one of the first, if not the first, in the North of England to be formally approved by the Ministry of Health. The transfer of hospitals involved extensive changes and in view of the reorganization necessary the county council sent a deputation of members and officials to certain newly built hospitals in Europe. Dr Potts brought back from this tour valuable information, which was presented in a detailed report. The outbreak of war in 1939 stopped all plans for hospital widening and building and Dr Potts turned his attention to the urgent needs of the ambulance and fire fighting services and to the provision of emergency hospitals and maternity homes in relatively safe parts of the county. Towards the end of the war failing health caused him to send in his resignation. The extensive staff and in particular, the health visitors regarded his resignation with dismay and learned of his death with unfeigned sorrow.

SIR ALMROTH WRIGHT

Dr Leonard Colebrook writes. For those of us who were privileged to work with Wright there will always remain the memory of his extraordinary intellectual vigour and his immense capacity for work. We see him quietly preoccupied during all the years of his life with one problem after another—often toiling away at his laboratory bench long after everyone else had gone home quite regardless of the meal that had been prepared for him hours before and of his own bodily weariness. He could not rest while any question was unresolved in his mind or an experiment unfinished. Quoting Emerson he used to say "God has given every man the choice between truth and repose." Wright had two chief aims: first, to bring the science in to the practice of medicine and secondly, to bring clear thinking to bear upon the big fundamental questions which concern us all—man's relation to his fellows, the principles of morality (especially intellectual morality), the concept of truth, etc.

For those of later generations who have not been familiar with his work it may be useful to have a list of the chief ideas on which he applied his fertile mind—and wrote about them. We can piece each of his many contributions may have in the end a body of knowledge it is safe to say that none of us could do better in presenting original ideas. Most of them contain a certain amount of detail and all are presented in his characteristic lucid, if not always easy style. The following list

is far from complete. I have compiled it chiefly from memory have given in some cases paraphrased titles, and sometimes have added brief comments (in brackets). Incomplete references are sometimes given, the rest can be found, for the most part, at the end of his book on "Technique," or I shall be happy to supply them. The order is roughly chronological.

- 1 "On the Physiological Element in Emotion" *Brain* 1895
- 2 "On Colour Shadows in Nature" *Nineteenth Century* 1895 (This paper has opened a fascinating new world to many lay people)
- 3 "On Citrating Cow's Milk for Infant Feeding" *Lancet* 1893 (Wright always regarded this as one of his most useful contributions to medicine)
- 4 "On the Principles of Microscopy" Constable, 1906 (A book recording his experimental examination of the optical principles involved in the microscope)
- 5 "On Anti Typhoid Inoculation and the Measurement of the Bactericidal Power of Human Blood" (A series of five papers in the *Lancet* and the *British Medical Journal* 1897-1901, which include the description of the first of his many micro methods of blood examination. These papers make a landmark in the history of medicine)
- 6 "On the Part played by Serum in Phagocytosis and on Measurement of the Opsonic Index" *Proc Roy Soc* 1903, 1904, and 1906
- 7 "On the Vaccine Treatment of Tuberculous, Staphylococcal, Streptococcal and other Infections" (An important series of papers chiefly in the *Lancet* and *British Medical Journal* 1904-1912, which develop Wright's conception of the physician as an immunizer)
- 8 "On Prophylactic Inoculation of Rand Miners against Pneumonia" Constable 1914 (This book describes Wright's work in South Africa and deals also with the logical methods which ought to be employed in evaluating therapeutic agents)
- 9 "On Woman Suffrage" A letter to *The Times* of March 27, 1912, and a book entitled, *The Unexpurgated Case against Woman Suffrage* Constable, 1913 (The letter to *The Times* is a remarkable statement in Wright's best prose of the anti-feminist position, which exerted a considerable influence at the time of the Adult Franchise Bill. The book is a further development of this theme)
- 10 "On the Physiology and Treatment of War Wounds," including (a) Studies on the factors which permit microbes to develop in such profusion in war wounds (b) Studies on the bactericidal activity of leucocytes (c) The treatment of wounds by hypertonic salt solution (d) A polemic on the treatment of war wounds by antiseptics in reply to Sir Watson Cheyne *Lancet* 1916, 2 (c) "On the Pathology and Treatment of Gas Gangrene" (This series of papers, in my view, comprise some of the best of Wright's medical work although much of it has never yet got into textbooks)
- 11 "On the Technique of the Teat and Capillary Glass Tube" Constable, 1912, revised in 1921 (A handbook of unique character for the medical research laboratory and the research ward embodying all the technical laboratory procedures developed by Wright and his co-workers up to the date of publication)
- 12 "On Intertraction" *Proc Roy Soc Series A*, 1921, 92 and 1926, 112 (These, and other papers, deal with what Wright regarded as a previously undescribed physical process governing the mixture of fluids of different densities, including some body fluids. Wright's interpretation of the phenomena observed was not accepted by some physicists, but he himself was never convinced that his interpretation was at fault)
- 13 "On the Growth of the Tubercle Bacillus in Human Blood and the Employment of this Procedure for the Study of Tuberculosis and Chemotherapeutic Remedies" *Lancet* 1924, 1 218
- 14 "On the Immunization of Blood *in vitro*, and its Use for Immuno transfusion" *Lancet*, 1923, 1
- 15 "On the Need to Abandon Much of the Immunological Doctrine Previously Regarded as Well Founded" *Proc Roy Soc Med* 1942, 35 161 (The doctrine abandoned includes much of Wright's own earlier teaching)
- 16 "On Induction and the Conduct of Experiments dealing with Causation" (This philosophical essay is included in the series of Studies on Immunization published by Heinemann (Vol 4) in 1943)
- 17 *Prolegomena to the Logic which Searches for Truth* (This book, published by Heinemann in 1941, is the prologue to a much larger book on philosophical questions which Wright was working on until the last month of his life and which is now almost ready for publication. At one time it took the form of a 'Dictionary of Principles' but in recent years he attempted in it to formulate a system of logic more applicable to the problems of the modern world than are the older systems of formal logic)

The preface gives a synopsis of the matters to be dealt with in the larger book, a glossary, and two or three preliminary chapters.)

Few men of any age can have left such a record of constructive intellectual effort and few medical men can have exerted so great an influence upon contemporary thought. When Wright was a young man physicians were still chiefly concerned with the relief of symptoms, treatment was still largely empirical, the bottle of mixture which had come down to us from the past was predominant. Even Pasteur's brilliant results with immunization had been obtained for the most part by hit and miss methods. Wright taught us to look beneath the surface at the 'sub perceptible' changes in the body—to trace the effect of drugs, vaccines, etc., upon the constituents of the blood rather than upon the whole man—and to measure the response to treatment. To day when we give penicillin or the sulphonamides we ask ourselves as a matter of course, what concentration in the blood our dosage will maintain and whether the infecting microbe is sensitive to the drug and we take trouble to ascertain these things. That changed attitude is due more, I think to Wright's influence than to that of any other man.

Although much of his teaching has not been widely accepted—and the trend of medicine in the last few years has been towards chemo rather than immuno therapy—the future may yet prove that the broad path of progress is along the lines Wright's vision and his unsparing labour have indicated to us. Before we reject his teaching we should do well to recall that some of the antityphoid vaccine he prepared for soldiers going to South Africa 50 years ago was dumped overboard by those who thought 'The Old Man' crazy.

Dr WILLIAM BYRON MILBANKE died at his home in Sunderland on April 11 at the age of 79. He had been at work in his surgery up to the day before his death. A student of Durham University, Dr Milbanke qualified in 1898 and had been in general practice for 48 years.

Dr A. A. McIntosh Nicol writes: On the death of Dr W. Milbanke the medical profession in Sunderland lost one of its oldest practitioners and the town one of its most respected citizens. He belonged to a past generation, and to the end he maintained that dignity of carriage and charming manner which so characterized him. Before the 1914–18 war he was a keen Territorial and was attached to the Durham Light Infantry but on account of his age he was not allowed to proceed overseas with that regiment. He did so later, however, with the Royal Artillery, and served in France and was mentioned in dispatches. He joined the British Medical Association in 1900, was chairman of the Sunderland Division in 1926–7, represented his constituency at the Annual Representative Meeting in 1928, and took a very keen interest in the affairs of the Division to the end of his life. He was much sought after for advice as his candour and fearlessness in debate were highly esteemed. He was not a man of many words, but when he did speak he spoke with sincerity and conviction. Dr Milbanke had intended to retire in 1939, but decided to carry on in view of the fact that so many of the younger men would be leaving for the Services. During the war he was medical officer at a first-aid post and was unfailing in his duty, attending at his post regularly in the midst of all the blitzes in this badly scarred northern town. To the end he was active and mentally alert and on the day before his death was seeing patients as usual. He died the death he would have wished, in harness to the end. We are all the poorer for his passing.

Dr JAMES KENNEDY MANSON died suddenly on April 13 at the comparatively early age of 57 years. Graduating from Glasgow University in 1914, Manson had a varied and interesting career. He saw much service as a captain, R.A.M.C., during the 1914–18 war. While in East Africa he became greatly interested in tropical medicine and, in collaboration with L. D. H. Thornton, prepared a report on relapsing fever which was later published in the *Journal of the R.A.M.C.* After demobilization he was in general practice in this country until, in 1923, he proceeded to India to join the medical service of the then South Indian Railway Company. He retired from that service in 1935 to take up general practice again in Peebles, Scotland. In 1940 he was posted back to the South Indian Railway as its chief medical officer. With the rank of major he served continuously until the end of 1945. During this period he was admitted as a Serving Brother of the Order of St John of Jerusalem. His health had been impaired during those latter strenuous years, but in August, 1946, he was appointed a deputy commissioner of medical services with the

Ministry of Pensions at their headquarters at Norcross, Lancs., which appointment he held at the time of his death. Of a kindly and unobtrusive disposition, James Kennedy Manson never spared himself in the interests of his profession. Music and literature were his hobbies. His memory will long be cherished by his many friends and former patients.—J.M.

Dr JOHN DEWAR ROBSON died at his home in Dumfries at the age of 79, on April 26. He qualified M.B. Ch.B. at Edinburgh in 1890, and soon afterwards acted as assistant to a practice in Wensleydale, where he did his round on horse back. Fifty years ago he settled in Dumfries and became honorary radiologist to the Dumfries and Galloway Royal Infirmary. He had to resign this post because his hands were affected by the X-rays, later the malignant areas were excised. He had been an active member of the British Medical Association for over fifty years and was chairman of the local Division in 1928–9. He was interested in shooting, fishing, football, billiards, skating, and bowling, at which last he was Scottish champion in 1907. He suffered fools badly, but was always ready to help youth and the poor. He was the doyen of the medical profession in Dumfries and remained in harness to within two months of the end. He was married twice, and his second wife, a son and a daughter survive him.

DR S. A. MONCKTON COPEMAN, F.R.S.

A memorial service for Dr S. A. Monckton Copeman, F.R.S., was held on May 7 at the Church of the Order of St John of Jerusalem. Major General R. J. Blackham gave the address and among those present were Sir Weldon Dalrymple Champneys, representing the Ministry of Health, Sir George Elliston M.P., the Society of Medical Officers of Health, Major General J. E. T. Younger, the Order of St John of Jerusalem, Dr Andrew Shinnie, the Westminster City Council, Dr A. L. Crockford, representing St Thomas's Hospital, Dr A. E. Hindle, the Zoological Society, Mr A. E. Roche, the Hunterian Society, Mr W. C. Hornby Steer, the Hampstead Borough Council, Sir Allen Daley, the L.C.C., Mr H. I. Gerrans, the Royal Institute of Public Health, Mr A. E. Porritt, the Provincial Grand Lodge.

Medico-Legal

FAILURE OF A RESTRICTIVE COVENANT

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A covenant in restraint of subsequent practice in the neighbourhood is a necessary part of every agreement between doctors to associate in practice. A retiring partner, the seller of a practice, or an ex assistant having gained an intimate knowledge of the practice would obviously be very dangerous competitors if they remained in the neighbourhood. Such covenants, however, need to be carefully drawn, for if the court considers that a covenant is unreasonable in one respect which is not severable from the rest the whole becomes invalid and the outgoing practitioner is not restrained from competition. The reports contain few cases which could guide draftsmen who consequently have had to devise forms which would correspond as nearly as possible with the spirit of the available decisions. The judgment of Mr Justice Evershed in *Routh v Jones* (1947, 1 All E.R. 179), which was confirmed by the Court of Appeal on April 18, has caused widespread interest by invalidating the form of restrictive covenant which has been commonly used by the British Medical Bureau in agreement between doctors, and is embodied in a very considerable number of existing contracts.

Two partners in a general practice in Okehampton, Devon, engaged an assistant in March, 1943. At the end of December he signed a covenant binding himself not to practise or cause or assist any other person to practise, in any department of medicine, surgery or midwifery, nor accept or fulfil any professional appointment, whether paid or whether honorary, within a radius of ten miles from the partnership address for five years after his assistantship ended. In March 1946, he left the service of the partners and bought a house in Okehampton intending to set up in practice. The partners moved the

HAEMATOPOLISIN

Hepolon is produced by special processes which conserve all the known haematopoietic principles of the whole liver. It approximates to the extract described by Gänsslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anemia but contains Whipple's factor, Wills's factor, riboflavin, nicotinic acid, and the haematine minerals of liver. It gives no reactions for histamine or undesirable protein matter.

Amperol 0.2cc. box 66. box 12.116 and box 21.72
Bottle 10.000. 10.000. 10.000.

HEPOLON

Contains in 1.0 c.c. the total soluble extract of 2.0 g. of liver

ALLEN & HANBURY LTD., LONDON, E.C.2.

LINEN Ligature THREADS

are made from the best flax—strong and of fine texture. This material has a very high tensile strength on the Surgeon's knot and is a thoroughly dependable non-absorbent ligature and suture product.

Linen Thread has been used for centuries throughout the world by the Medical Profession.

Available from leading surgical supply houses.

For the treatment
of Lupus and Arthritis

Radiostol is calciferol in its purest form, it is suitable therefore, for administration in the large doses necessary in the treatment of lupus vulgaris and arthritis. Calciferol itself is not entirely free from undesirable properties when given in the huge doses frequently recommended but it is essential that it should be entirely free from the more toxic products of irradiation.

Radiostol is issued in capsules each containing 50,000 i.u. (for use in the treatment of lupus vulgaris) and in solutions containing 100,000 and 200,000 i.u. per gram respectively (for use in the treatment of arthritis). Radiostol is available also in solution (Liq. Calciferolis B.P.) and in pellets each containing 3000 i.u. for the prevention and treatment of rickets.

EFFICIENT Hormone Therapy

Fundamental researches on the ovarian and testicular hormones have secured their preparation in pure, highly concentrated, accurately standardised forms suitable for logical and effective use in human therapeutics. Further, their successful syntheses have made adequate quantities available at greatly reduced prices. British Schering's complete range of reliable hormone products worthily reflects these great advances.

Antuitrin 'S'

*A standardized solution
of chorionic gonadotrophin*

In the female the effect of Antuitrin 'S' is mainly luteinizing, and it is indicated in functional uterine bleeding, dysmenorrhoea, amenorrhoea, oligomenorrhoea, and habitual and threatened abortion.

In the male, Antuitrin 'S' acts on the interstitial cells of the testes, increasing secretion of the male hormone, and is used in the treatment of cryptorchidism, impotence and aspermia.

In both sexes it has been shown to be valuable in delayed puberty, genital infantilism, acne vulgaris, adipose genital dystrophy (Fröhlich's syndrome), and in some cases of sterility.

Antuitrin 'S' is supplied in rubber capped vials of 10 c.c. (100 International units per c.c.) and 5 c.c. Concentrated Solution (500 International units per c.c.)

Medical Notes in Parliament

Food Situation

Lord WOOLTON in the House of Lords on May 7, called attention to the growing danger of a serious shortage of food in this country. He said the housewife was weary and alarmed and he doubted whether the heavy workers of the country were getting enough of the right sort of food, and particularly of fats to enable them to give increased production. The previous day he had read in the medical Press a special article by a Dr Frank Bicknell which began, "England is dying of starvation." In the Coalition Government the one foundation of the nation's food supplies had been the securing of an adequate amount of fats. Experience convinced him that this job of providing adequate food for the people of the country was not being done. The meat position was very serious. The scheme of bread rationing had broken down and the system of couponing did not work. That was what the bakers told him. The country would continue to have a fuel shortage, but if it also had a food shortage the Government would deserve the censure of the people. The time had come to make an end of this low standard of living.

Lord HENDERSON replying for the Government said fresh calamities might be in store as unforeseen as the blizzards and floods of last winter, but the prospects of a fair harvest in the United Kingdom were better than anyone a month ago thought possible. The country could count on a good supply of wheat from Argentina's new crop, and the United States promised to send a large quantity during the three months July-September. The Government expected to provide a balanced and increasing ration for an expanding livestock population. So far as bacon, eggs, butter, margarine, cooking fats, milk, and cheese were concerned there was every reason to expect that the supply would continue during the remainder of this year at least as good as it was now. Although oils and fats were still subject to world shortage the Government expected to maintain the fats and soap rations through 1947 at their present level. The supply and consumption of milk continued to mount and the sale of liquid milk to the public steadily increased. The supply of eggs this year should be maintained at its present level and an increasing proportion of it consisted of eggs in shells. With sugar the country would do at least as well this year as last. Meat was the foodstuff of which the supply was most difficult. The Government was buying every ton of imported meat which it could afford, but it was by no means certain to make good the deficiency in home output and the rations might have to be reduced to the level ruling in May, 1946. The Government looked forward to a large increase in supplies of fish, and the quantities of potatoes available for consumption before the end of the season were likely to be adequate. By mid-June there should again be a reasonably plentiful supply of vegetables. The lateness of the spring increased the chances of a good fruit crop and imports of fruit were likely to exceed those of last year by not far short of 50%. The Government, to the utmost of its powers, would see that the food supplies of the people were maintained, and where possible raised.

Lord BEVERIDGE said the Government was too apt to be content with rationing. They ought not to aim at rationing indefinitely. Rationing was unjust to the individual and checked production.

Lord HARLECH said the bread ration in Britain was much better than in most European countries and Britain was better off than most countries for potatoes, but worse off for vegetables. The meat supplies of this country were quite inadequate for the heavy workers. It was essential that the protein constituent of the ration should go up.

Lord RUSHOLME said there could be no foundation for a statement that food supplies available to the British people were down to the level of those of the German people. So far as meat, jam, cheese, sugar, and eggs were concerned, consumption per head at present was larger than in 1945, and so far as jam, cheese and milk were concerned consumption was larger per head than in pre-war days. There was a world wide shortage of fats and all importing countries were suffering.

Agricultural Difficulties

The debate was resumed on May 8 by Earl DE LA WARR. He said the losses of winter corn on the Continent were a great deal more serious than in Britain.

The Earl of HUNTINGDON said that in the last few months the British agricultural industry had suffered a major disaster which would affect the diet of the people. There was a serious reduction in the acreage of wheat, the acreage in sugar beet

was likely to fall, 75,000 tons of last year's crops and potatoes had been destroyed and some reduction must be expected in this year's supplies of potatoes. Until July many vegetables were likely to be in very short supply.

Lord LAMBERT said that in Devonshire the agricultural workers were all underfed and the manual worker was also underfed. They had colds and chills because they had not a sufficient diet.

Lord LLEWELLIN said that when people asserted the nation was getting more nutritional value in the form of milk the House must look at the fact that there were not many more cows, and that the nation was not getting the butter and cheese. Things had got worse since a consumption level inquiry had been held in 1943. It would be better to take the really bad meat off the ration. He was delighted to see that fish was now coming in, but fish was of no avail without fats in which to fry it. Bacon unfortunately was also down.

Lord ADDISON agreed with Lord Woolton that the housewife was weary and tired. Nobody would rejoice more than the Government if the diet could be made more interesting and varied, but the fact was that the world was short of food. The assertion which Lord Woolton had quoted from Dr Bicknell that England was dying of starvation was a monstrous falsehood. How did Dr Bicknell know how the unemployed were fed before the war? The figures of Sir John Boyd Orr and Mr Rowntree, and those which Lord Beveridge used in drawing up his own scheme showed that before the war 77% of the population were so poor that they could not buy enough food. That was not the case to-day. Dr Bicknell had said that the average person in Britain got 2,100 calories a day. The figure had been checked at the Ministry of Food and it actually was 2,900 calories. Dr Bicknell said that the unrationed food including potatoes, gave only 400 calories. Lord Addison understood that they probably gave a good deal more.

Lord WOOLTON said Lord Addison had found it necessary to use violent language about a statement made by a distinguished member of a profession to which Lord Addison used to belong. If that statement was wrong then the Government had ample means of correcting it. He himself wondered whether he had not minimized the danger of food shortages during the next three months. He begged the Government to take all the steps in its power so that the people did not have to suffer hunger during the coming months.

The debate concluded.

National Service and Doctors

During the all night sitting on the National Service Bill on May 7, Clause 9 was ordered to stand part of the Bill.

Col STODDART-SCOTT said that since the number of doctors who qualified each year had been just over 3,000 there would be far more doctors than were required for the Services. There would be 1,500 doctors fit to serve, and a force of 1,500,000 would be required to occupy them. The thing to be avoided was having Service doctors unemployed or partially employed while there were overworked doctors in general practice. There would also be in the Services more specialists than were required.

Mr ISAACS said the Government did not wish to denude the country of doctors by taking them into the Forces. The Medical Priority Committee would be consulted on the best use of the available medical services. It might be best in some areas for the doctors to serve a shorter period or to be exempt. It might be best to say, 'There are 1,000 doctors, but we want only 500.' The Government would do the same with the specialists. It did not want to take a man into the Forces because he was a specialist. It would want to take the kind of specialist for which the Forces were looking.

Fowl Pest—Up to May 2 the number of outbreaks of fowl pest confirmed by the Ministry of Agriculture was 147. In addition 160 suspected cases had on investigation proved to be negative. About 16,000 birds had been slaughtered at an approximate cost in compensation of £12,000. Since the most likely source of infection was uncooked poultry waste, Mr Tom Williams has made it obligatory for all poultry keepers to boil such materials before allowing their birds to have access to them. The importation of live birds and hatching eggs from countries in which fowl pest is prevalent is not being permitted. Officers of his Department and of the Ministry of Food are examining the possibilities of minimizing the risk arising through the importation of dead poultry.

Medical Students—Asked on May 8 what additional facilities were being provided for training medical students in view of the shortage of women doctors Mr BEVAN replied that all provincial medical schools admitted women students up to between 20% and 30% of the annual intake. The London schools had all now agreed to take a proportion of women as soon as accommodation could be provided. This should be ready for the 1947-8 session.

Condemned Prisoners—Asked on May 8 by whom application had been made for an examination of the mental condition of Thomas John Ley, Mr EDE said the consideration of the question whether a medical inquiry should be held into the mental condition of a prisoner under sentence of death did not depend on the receipt of an application. It was his duty in every capital case to consider whether any question arose as to the prisoner's state of mind and to order a medical examination when he had reason to think further inquiry desirable.

Mr LANG pointed out that the defence of insanity had not been raised at the trial nor in the Court of Appeal. He asked Mr EDE to assure the House that this was not a trial by doctors to supersede a trial by jury. Mr EDE said he was not bound by what had been submitted to the Courts. If he had any doubt of the mental stability of a person sentenced to death his duty was to order a medical inquiry. If that inquiry took a certain course the matter was then completely out of the hands of the Home Secretary.

Sick Soldiers—The current instruction regarding men waiting to report sick as ill soldiers will not parade for this purpose but will inform the orderly NCO and proceed independently to the M.I. room at a specified hour. Arrangements for transport are made if the M.I. room is at some distance from the unit lines.

Medical News

The jubilee dinner of the Chelsea Clinical Society will be held at South Kensington Hotel, Queensgate Terrace, S.W. on Tuesday, May 20, at 7.30 p.m. for 8 p.m.

A discussion on the training of contact lens practitioners which was opened by Mr Williamson Noble, F.R.C.S., was held on April 21 at a meeting of the Contact Lens Society. Prof Ida Mann presided.

A general meeting of the Middlesex County Medical Society will be held at Harefield County Hospital on Friday, May 23, at 3 p.m., when there will be demonstrations of cardiopneumocentesis for pulmonary tuberculosis and massive doses of penicillin in the treatment of suppurative pneumonitis. At 4.15 p.m. three short papers on 'Blood Changes in Tuberculous Meningitis', by Dr L. F. Houghton, 'Some Observations on Bronchial Carcinoma', by Dr J. C. Roberts and 'Protein and Tuberculosis', by Dr I. Nassau, will be read.

The Manchester and District Medical Golfers Association will hold its annual competition at Hale Barns, Cheshire, on June 3. Particulars may be obtained from the Hon. Secretaries, Manchester and District Medical Golfers Association, c/o British Medical Bureau, 33, Cross Street, Manchester, 2.

The annual meeting of the members of the Royal Medical Benevolent Fund will be held at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W., on Thursday, June 5, at 4 p.m., when the financial statement for the year ended Dec. 31, 1946, will be presented and the officers committee and honorary auditors elected for the current year.

A congress will be held in Prague from June 11 to 15 to celebrate the fiftieth anniversary of the Czechoslovak Stomatological Society. On June 11 and 13 the tenth annual congress of the A.R.P.A. Internationale will also be held in Prague. The official languages of the Czechoslovak Stomatologic Congress will be Czech and Slovak. Lectures announced in advance may be spoken in English or French. Those wishing to attend should apply to Spolek českých zubních lékařů, Praha II, Sokolská 31, Lékarský dům.

Mr Bernard W. Williams has been appointed Medical Adviser and Dean of the Medical School of the University of the West Indies from Jan. 1, 1947. Mr Williams was born in Jamaica in 1895 and was educated at Exeter College, Oxford and St Thomas's Hospital. He won the Radcliffe Prize for Medical Research in 1926 and was Hunterian Professor in 1927. He was examiner in pathology to the R.C.S. and in surgery to Oxford University and Sub Dean of the Medical School at St Thomas's.

The Chinese Medical Journal founded in 1909 and suspended during the war, reappeared on May 1 with a monthly issue of 5,000 copies. Printed in Chinese, it is published in Shanghai.

The following members of the medical profession were recently elected Fellows of the Royal Society of Edinburgh: Hamilton Bailey, F.R.C.S.; George Howard Bell, M.D.; Group Capt. Gerald Strain Marshall, O.B.E., R.A.F. (ret.), and George Ranken Tudhope, M.D.

Dr John Dale, Chief Health Officer to the Melbourne City Council, has been granted six months' leave of absence to study public health administration in Britain.

At the Socialist Medical Association's annual general meeting on May 11 a resolution was passed advocating the setting up of permanent day nurseries and nursery schools. Dr Somerville Hastings referring in his presidential address to the NHS Act, said that the Minister of Health's views were sound but that he was less happy about some of his advisers. The Association considered that large buildings in all areas should be adapted as temporary health centres and that the building of new centres in selected areas should be started immediately.

Dr A. P. Cawadinas, OBE, has been awarded the rank of Knight Commander of the Royal Hellenic Order of the Phoenix by the King of the Hellenes.

EPIDEMIOLOGICAL NOTES

Smallpox

In the original reports of the outbreak at Bilston, Staffs., it was suggested that the disease imported from India was variola minor (April 19 p. 549). This has proved to be incorrect and most of the cases have been variola major of moderate severity. An unvaccinated labourer, not included in the list of contacts, died in hospital on May 2. The onset in this case was on April 25 and the rash appeared on April 29 (May 10 p. 664). Now his wife vaccinated in infancy 64 years ago, and his son-in-law aged 30 and unvaccinated have developed the disease while under surveillance. Both were vaccinated on May 2 after their recent exposure to infection.

In Cosely U.D., which is near Bilston, a woman aged 78, in poor health and confined to her house with bronchitis for several weeks developed high fever about May 1 and pneumonia was diagnosed. A rash, first noticed on May 7, was thought to be associated with chemotherapy but by May 9 had become semiconfluent. On this day the patient, now very ill, was removed to a smallpox hospital. It is reported that the original case in the Bilston series had visited this patient's residence about a month ago. Details are not yet available, but this information may lead to a satisfactory explanation of the occurrence at Bilston of cases apparently outside the direct line of contact.

A case of smallpox in Sheffield cannot at present be associated with a known source. An unvaccinated schoolboy aged 11 and living in a tenement house sickened on May 1 and developed a rash on May 4. The diagnosis of smallpox was confirmed and the patient removed on May 10. Fortunately he had been confined to his bed since the onset.

Discussion of Table

In England and Wales infectious diseases were less prevalent and decreases were recorded in the notifications of measles 1,073, acute pneumonia 81, whooping cough 73, scarlet fever 38 and cerebrospinal fever 17. An increase of 15 in the cases of dysentery provided the only exception to the downward trend.

A fall was recorded in the incidence of measles throughout the country, and the largest declines were Lancashire 243, Staffordshire 240 and Gloucestershire 104. A small fall in the notifications of whooping cough was general and the only exception was an increase of 59 in Essex. The only changes of any size in the local returns of scarlet fever were a decrease in Middlesex 30 and a rise in Glamorganshire 23.

The decrease of 7 in the notifications of diphtheria reduced the total to one below the record low level of twelve weeks ago. The only significant change in the local incidence of dysentery was a rise of 12 in Lancashire. In the outbreak in Surrey 15 more cases of dysentery were recorded, bringing the total for the past three weeks to 53.

In Scotland decreases in the notifications were reported for whooping-cough 77, measles 61, and acute primary pneumonia 21. There were small rises in the incidence of scarlet fever 24 and cerebrospinal fever 12. The increase in cases of scarlet fever occurred in the western area, while the increase in cerebrospinal fever was contributed by the eastern area.

In Eire a fall was recorded in the incidence of most infectious diseases—whooping cough 14, diarrhoea and enteritis 9, primary pneumonia 5 and scarlet fever 4.

In Northern Ireland increases were recorded in the notifications of measles 18, scarlet fever 9, and whooping cough 7.

Week Ending May 3

The notifications of infectious diseases in England and Wales during the week included scarlet fever 873, whooping-cough 2,033, diphtheria 186, measles 8,442, acute pneumonia 516, cerebrospinal fever 52, dysentery 122, smallpox 1, paratyphoid 1, typhoid 1.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 26.

Figure of Principal Notifiable Diseases for the week and those for the corresponding week last year for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (in italics, London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	64	8	31	3	—	48	6	32	—	—
Diphtheria Deaths	175	22	50	25	9	389	27	104	42	1
Dysentery Deaths	61	4	19	—	—	163	25	63	—	—
Encephalitis lethargica acute Deaths	—	—	1	—	—	—	—	1	—	—
Erysipelas Deaths	—	—	33	16	1	—	—	40	8	—
Infective enteritis or diarrhoea under 2 years Deaths	72	9	14	19	5	56	6	2	42	14
Measles* Deaths	7,962	408	235	46	36	2,793	1054	354	29	—
Ophthalmia neonatorum Deaths	75	8	24	—	—	50	5	24	—	—
Paratyphoid fever Deaths	1	—	—	1(A)	—	5	—	—	—	—
Pneumonia influenzal Deaths (from influenza)†	647	43	5	9	5	654	39	11	21	—
Pneumonia primary Deaths	21	5	3	—	—	18	2	1	3	—
Polio encephalitis acute Deaths	—	—	231	25	12	—	28	188	28	14
Polio myelitis acute Deaths	1	—	—	—	—	—	1	—	—	—
Polio myelitis acute Deaths	6	2	—	5	—	5	1	—	1	—
Puerperal fever Deaths	—	1	10	—	1	—	—	23	—	—
Puerperal pyrexia‡ Deaths	136	8	11	—	2	148	12	17	—	—
Relapsing fever Deaths	—	—	—	—	—	—	—	—	—	—
Scarlet fever Deaths	892	76	150	22	42	1,054	104	147	29	—
Smallpox Deaths	—	—	—	—	—	—	—	—	—	—
Typhoid fever Deaths	6	1	—	3	1	4	—	—	2	—
Typhus fever Deaths	—	—	—	—	—	—	—	—	—	—
Whooping-cough* Deaths	2,044	256	322	74	26	1,669	139	76	36	—
Deaths (0-1 year) Infant mortality rate (per 1,000 live births)	472	71	65	21	17	354	50	53	34	—
Deaths (excluding still births) Annual death rate (per 1,000 persons living)	4,788	755	574	212	132	4,553	662	578	197	1
Live births Annual rate per 1,000 persons living	10,155	1626	1317	444	351	8,303	1202	1067	454	2
Stillbirths Rate per 1,000 total births (including stillborn)	266	33	30	22	—	235	32	40	36	—

* Measles and whooping-cough are not notifiable in Scotland and the rate are therefore an approximation only.

† Includes primary form for England and Wales (London (administrative county) and Northern Ireland).

‡ Includes puerperal fever for England and Wales and Eire.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

"Hereditary" and "Familial"

Q—What are the differences between the terms hereditary disease and familial disease ?

A—The characteristic features of human pedigrees associated with the different types of hereditary transmission were known empirically long before the rediscovery of Mendel's work. The use of the terms 'hereditary' and 'familial' is a survival from those pre-Mendelian days. A regularly expressed dominant gene is handed on by its bearer necessarily to an affected person, to half his children on the average. Normal persons cannot carry the gene and so cannot transmit it. Simply inherited abnormalities are rare, hence affected persons almost invariably marry normals. So we observe the typical dominant pedigree in which every affected person has one affected parent, and affected persons have on the average affected and normal children in equal proportions. The most striking feature is the evident direct transmission from generation to generation. Hence the use of the word 'hereditary' to describe the pedigrees of such conditions as multiple telangiectasia, piebalding, or brachydactyly.

In contrast a recessive gene manifests itself only when present in a double dose, that is to say, the abnormal gene must be received from both parents. Such a gene may be transmitted through many generations of outwardly normal carriers. Occasionally a man and woman marry who both happen to carry the same recessive gene, then, on the average, one-quarter of their children will manifest the abnormality. The outwardly normal offspring, and the abnormal ones also (if the condition is compatible with life and reproduction) will rarely happen to marry partners who also carry that gene. So the defect seems to vanish again, not to reappear for perhaps many more generations. Therefore the typical finding is a large number of normal ancestors and collaterals, then the sudden appearance of a sibship containing one, two, or more affected children, then normal descendants and collaterals. This is what is observed in such conditions as amaurotic idiocy, albinism, or xeroderma pigmentosum, to which the word 'familial' was applied.

To-day, the mechanism being fully understood, it seems better to use the words 'dominant' and 'recessive'. There is perhaps no harm in using the older terms if it is desired to convey to those unfamiliar with genetics the salient features of the two types of transmission, but, of course, a condition described as 'familial' is 100% inherited, just as is a condition described as 'hereditary'.

Leuconychia

Q—What are the aetiology and treatment of transverse linear chalky white markings on the nails? The marks start at the base of the nail and enlarge as they grow towards the tip.

A—Leuconychia is due to periodic interference with the growth of the nail at the nail matrix as the result of trauma or toxic, circulatory or nervous influences. Treatment should be directed to the cause. The trauma of manicuring the nails should be considered.

Arsenicals in Congenital Syphilis

Q—What are the dosages of neoarsphenamine, sulpharsphenamine and bismuth for the treatment of congenital syphilis at different stages ?

A—In the treatment of late congenital syphilis the dosages of neoarsphenamine, sulpharsphenamine and bismuth are essentially the same as those used in acquired syphilis, in early congenital syphilis the individual dose of each drug is usually calculated in mg per kilo of body weight of the patient. In the case of sulpharsphenamine Earle Moore recommends 5 to

10 mg per kilo for the first dose, rapidly increasing to the desired maximum of 25 mg per kilo, Lees recommends 10 mg per kilo during the first year of life, while McLachlin says this latter amount should not be exceeded. The dosage of neoarsphenamine is much the same though this drug is seldom used in very young infants. The usual dose of bismuth is 2 to 5 mg per kilo, starting with the lower dose. A course may last about sixty days and the arsenic and bismuth may be administered concurrently in weekly doses. Four such courses should be the minimum for early congenital syphilis more are often required, particularly if the serum reactions are slow in reversing.

Ps. procyanea and Penicillin

Q—The *Pseudomonas procyanea* is said to be insensitive to penicillin. What is the best method of eradicating it from an infected urinary bladder ?

A—This organism is one of the most resistant to penicillin of all bacteria, it forms penicillinase and thus destroys the drug. It is therefore useless to give penicillin even in large doses, for a urinary-tract infection so caused. The sensitivity of *Ps. procyanea* to sulphonamides is variable. This should be tested with the patient's own organism if possible. If not sulphathiazole, 1 g four times a day might be tried. If this treatment does not succeed within a few days it should be discontinued. Streptomycin, if available is the most effective drug although in a minority of cases it fails owing to the acquisition of resistance to it by the infecting organism.

Dental Extraction in Hyperpletic

Q—A married woman of 64 has a mouth full of rotter stumps two of which ooze pus. Her blood pressure is 230/140 mg Hg and the heart sounds are strong regular and slow, her urine is clear. Is there any sound reason for the advice she has been given not to have nitrous oxide? If so what anesthetic or other procedure would you suggest?

A—In the hands of a competent anaesthetist nitrous oxide with oxygen administered through a nasal inhaler should be sufficient provided that the patient's general cardiovascular condition apart from the hyperplepsia, is sound. Should she be unwilling to have nitrous oxide, a local analgesic could probably be used, though it would be advisable to omit the usual adrenaline in the solution. In deciding which method is preferable much depends on the position and firmness of the teeth and the degree of surrounding sepsis.

Treatment of Seborrhoea

Q—In a case of seborrhoea soap spirit, salicylic acid and sulphur ointment and lotion have given only partial relief. The scalp is still thick with scales and the rash in the axillae and genito-crural regions persists. Is there a newer method of treatment?

A—Acute seborrhoeic dermatitis of the type described is symptomatic of general ill health and each case is an individual problem. There may be underlying foci of infection or metabolic or nutritional imbalance. Psychogenic factors are commonly of major importance, hormonal deficiencies are also often important. In a general way a high intake of protein and of vitamin B with restriction of carbohydrates, fluids, and salt a mineral alkaline mixture, phenobarbitone in small doses, and possibly oestrogen therapy may help.

Secondary Effects of Vaccines

Q—Does antityphoid inoculation boost resistance to other infections? Does it ever activate a latent gonococcal infection? On theoretical grounds are such secondary effects likely to be significant?

A—There is no known antigenic relationship between organisms of the enteric group and others quite unrelated which would suggest that any specific immunity to other diseases is likely to be produced by TAB vaccine. Whether the administration of bacterial vaccines of almost any composition has some non specific effect on resistance to infection generally is uncertain, to assume that this is so seems the only way to explain the effects claimed for various vaccines for

many years past. A large dose of a vaccine may cause a transient exacerbation of any chronic infection, including gonorrhoea.

Thorium X for Nacvi

Q—*Thorium X has been used effectively in babies afflicted with capillary nacvi. May I have details of its use and indications?*

A—Thorium X suspended in a varnish, ointment, or in alcohol may be applied at monthly intervals. The strength commonly used is 1,000 electrostatic units per ml. Reference should also be made to another answer given in the *Journal* of April 12, p. 516.

Definition of "Psychopath"

Q—*What is a psychopath?*

A—The best definition of a psychopath is that of Kurt Schneider: an abnormal (that is unusual) personality who by reason of his abnormality either himself suffers or causes society to suffer. In Anglo-American psychiatry the two parts of this definition tend to be separated. The individual who himself suffers under his abnormality is called neurotic, while he who causes society to suffer is called a psychopath. It is, however, important that the same man at different times in his life-history may show both of these two aspects of abnormality, and that the question whether society has or has not suffered may be very differently answered by his contemporaries and by posterity. Any useful definition must have a quality of arbitrariness. Schneider pointed out that abnormal and psychopathic personalities came within the range of normal human variation, and the distinction between normality and abnormality is quantitative and not qualitative.

Tinnitus

Q—*A woman of 53 has thyrotoxicosis and tinnitus referred to the right ear which is slightly deaf. Her blood pressure is 170/90 mm. The thyrotoxicosis has responded to methyl thionuracil and she is well again except for the tinnitus which she describes as burning and thumping. What treatment do you advise?*

A—The description of the tinnitus suggests an arterial origin, therefore treatment should first be directed to reducing the slight hypertension. If such drugs as sodium nitrite or nitroglycerin prove unavailing, nicotinic acid or nicotinamide in large doses should be tried. Histamine diphosphate injections are sometimes helpful. But in many cases there is no prospect of cure, and the changes must be rung on the various sedatives, of which phenobarbitone and the bromides are the most useful.

Raven's Intelligence Test

Q—*Is Raven's test—the 'progressive matrices'—satisfactory for estimating general intelligence, or is it complicated by a special factor?*

A—A valuable summary of extensive experience in the Forces of the use of the Raven progressive matrices has been given by P. E. Vernon in a recent paper (*Occup. Psychol.* 1947, 21, 53). Numerous factorial analyses have shown that the scale is an almost pure *g* test, but that the visuo-spatial or *k* factor is also involved to a small extent. It is stated, however, that the test proved somewhat disappointing in practice. Only when the *k* factor was specially concerned, as it is in certain mechanical duties, did the Raven matrices add appreciably to the information given by other intelligence tests. Its reliability is rather low, and it is especially susceptible to non-intellectual influences such as age and temporary emotional stress. Furthermore it appears to function unequally at different parts of the range of intelligence. Among the bright it correlates highly with the more lengthy scales and probably represents for many purposes a useful twenty minutes of testing time. Among the below average however its reliability is low, hence it appears to be of little use for sorting out backwardness, dullness and high grade mental deficiency. Among the very dull of all it seems to become more efficient once again, but it is doubtful whether at this part of the range it is contributing anything that could not be better measured by other means.

Letters and Notes

Continental Holidays for Invalids

Dr A. PINEY (London, W1) writes: I have always regarded myself as a careful reader of the *Journal*, but I have not seen (and cannot trace) any reference to medical certificates for invalids who in their doctor's opinion, would benefit from a holiday on the Continent but for whose stay £75 would be insufficient. The national newspapers mention that in some cases the Treasury may allow a greater expenditure in order that the holiday may be of sufficient length. The treatment of pulmonary tuberculosis in Swiss sanatoria is an apparently reasonable example, especially as our own sanatoria are so full. In the case of milk and eggs there is, I understand, a committee one of whose duties it is to draw up a list of malades for which such supplements are permitted, while another is to advise the Minister of Food in doubtful cases. Does a similar committee exist to advise the Treasury? Is there a list of maladies that entitle patients to such certificates for Continental holidays? And is there any considerable body of medical opinion that advocates the treatment of thrombosis by foreign travel?

* * We understand from Exchange Control that the expenditure of patients going to Switzerland is not limited provided adequate medical evidence supports their going to that country. They should notify the authorities of the approximate time they intend to spend there and the sum required. Patients should apply on Form T2, which should be accompanied by a medical certificate.—ED, B.M.J.

Summer Prurigo

Dr J. B. SPEARMAN (Gillingham) writes: I am a sufferer from summer prurigo (April 19, p. 651). When in the R.A.M.C. I was posted for tropical service, I nearly used it to "dodge the column." Yet in India and Burma I had no trouble at all, and could sun-bathe with everyone else. Then with return to "civilian street" it reappeared. I usually reckon to see it appear during Whitsuntide, but this year it came out on the Sunday after Easter. I wonder if any of your readers can suggest a reason for its non-appearance in the Tropics? Perhaps it was graduated exposure on the voyage out, I kept out of the sun as much as possible in those weeks—but why should it return in this country?

Edentulous Halitosis

Dr F. COLEMAN (London, W1) writes: A more likely cause for an unpleasant taste in the mouth in edentulous patients is the wearing of dentures at night, and especially if they are constructed of vulcanite. A trained observer can always tell whether patients wear their dentures at night from the inflamed condition of the mucous membrane of the palate and gums. In the case of full dentures this represents an area of approximately 10 sq. in. (65 sq. cm.) of inflamed tissue (i.e., five or six in the upper and four or five in the lower). A vulcanite denture is more harmful in this respect owing to its porosity (increased if the rubber is insufficiently vulcanized), which harbours food and debris, apart from the rough surface it presents to the underlying tissues. The treatment should be to instruct patients to remove their dentures at night and to cleanse them, and if this fails to give relief to substitute an acrylic resin or a metal based denture for the vulcanite denture. Retained roots and buried roots should be excluded as suggested, but are less likely to be the cause of the condition under discussion (*Journal* May 3, p. 625). It should be noted that the word "halitosis" suggests smell rather than taste, although the two conditions are no infrequently associated.

THE EPIDEMIOLOGY OF TUBERCULOSIS*

By

JOHN W S BLACKLOCK, MD, FRFPS

(From the Department of Pathology and Bacteriology, the University and Royal Infirmary Glasgow)

The earliest observation on the contagious nature of tuberculosis occurs in the Ordinances of Manu in India, thirteen centuries B.C. In these, pulmonary consumption and swelling of the glands of the neck are declared to be unclean, incurable diseases. Those who wanted to marry are cautioned not to select a spouse from a consumptive family even though the family had a good lineage and possessed great wealth. These laws show a knowledge of tuberculosis, and as the disease was regarded as an impediment to marriage it seems likely that it was regarded as contagious. In Europe the earliest reference to the contagious nature of tuberculosis was made by the Greek orator Isocrates in his *Aegineticus* (§ 29), written about 390 B.C. In this he states "The majority of those who had nursed this disease [phthisis] had themselves fallen victims to it." The Hippocratic school, however, did not generally subscribe to this view, preferring the idea of the tuberculous diathesis which has persisted even to the present day. About one hundred years later Aristotle realized that consumption could be spread by close contact with the diseased person. Galen and Avicenna held similar views. It is more than a tragedy that these early Greek observations were disregarded and forgotten in later centuries, for it was only towards the end of the seventeenth century that in Latin countries such as Spain and Italy the contagious nature of the disease was again being recognized. In Britain, Edward Mainwaring was possibly the first to assert that tuberculosis was spread by contact, as in 1667 he wrote "You must not frequently converse with a phthisical person whose unwholesome breath may infect the sound by drawing in putrid vapours which the other breathes forth, but above all a phthisical bedfellow is most dangerous to affect a sound person and chiefly to be avoided."

Later, in 1694, Richard Morton in his book *Phthisiologia*, which is an outstanding presentation of the symptomatology of tuberculosis, wrote "A contagious principle also propagates the disease, for, as I have found by experience, an affected person may poison a bedfellow by a kind of miasm like that of a malignant fever." Towards the middle of the nineteenth century, however, leaders of the profession like Bright and Addison (1839), also Graves (1843), almost completely disregarded the contagiousness of tuberculosis, and attached great importance to diathesis. This unparalleled reverence for the past with its diathesis had so dominated men's minds that little or no progress had been made for centuries regarding the true nature of the disease. Laennec (1826), though he unified the whole

concept of tuberculosis by asserting that wherever tubercles occurred the disease was tuberculosis, was of the opinion that at least in France tuberculosis was not usually contagious. That tuberculosis could be produced in animals by inoculation with tuberculous material was shown in 1843 by Klencke, and in 1868 Villemin finally proved experimentally that tuberculosis was an infectious disease. It was Villemin who first showed that tuberculous material from bovine sources was more virulent for rabbits than that from human. In 1867 William Budd, of North Tawton, as a result of a study of the geographical distribution of consumption in past and present times, concluded "The tuberculous matter itself is (or includes) the specific matter of the disease and constitutes the material by which phthisis is propagated from one person to another and disseminated throughout society." Even after the discovery of the tubercle bacillus by Koch in 1882 we find from the Collective Investigation Record (British Medical Association, 1883) that many British physicians reported that they had never observed a case of probable transmission of the disease from a case of phthisis. Later Theobald Smith (1896, 1898) reported the existence of "a distinctively human or sputum, and a bovine variety of tubercle bacillus."

Though Koch proved that the tubercle bacillus was the *causa peccans* and stressed the importance of inhalation of infected sputum in the spread of the disease, it is strange how in 1901, while accepting that human and bovine types were different, he yet concluded that the latter was rarely pathogenic for man. Koch (1882) had undoubtedly found the bovine bacillus in human disease, for he had obtained from a case of caseous pneumonia (No. 27) a culture of tubercle bacilli which after inoculation into the anterior chamber of the eye proved virulent for rabbits. In 1911 the British Royal Commission proved conclusively that the bovine bacillus was a definite cause of tuberculosis in man. It is not surprising that Koch went astray when we consider the relative rarity of primary abdominal tuberculosis in Germany as compared with this country. Indeed, Koch himself in his address gave post mortem statistics from various German sources to support the rarity of this condition. At a later date Ghon and Kudlich (1930) found in 2,114 cases of tuberculosis in children in Central Europe a primary intestinal infection in only 24 (1.14%) and tonsils infection in 2 (0.09%).

Cycle of Infection in Human and Bovine Tuberculosis

The two chief varieties of tubercle bacilli to be considered are the human and the bovine types, as they are almost solely responsible for disease in man and in animals.

* A Special University Lecture in Pathology delivered in the University of London on March 6 1947

The avian may be dismissed, owing to the rarity of this type of infection in the human subject (Gloyne, 1933, Feldman, 1938, Bradbury and Young, 1946). The human type passes from man to man, more often by droplet infection than through the agency of dried sputum.

Infection with the bovine type is found chiefly in cattle, though many other types of animals and also man are liable to be infected. The chief mode of spread in cattle is by droplet infection, and thus, as in man, the primary lesion is most often in the lungs. Man is infected with bovine bacilli chiefly through the ingestion of contaminated milk, though air-borne infection is also possible, as is well exemplified in the cases of bovine conjunctival tuberculosis in millers reported by Jensen *et al* (1940). The cycle of infection, however, does not stop there (Fig 1), as it has

FIG 1—The cycle of infection in man and in animal

been observed that bovine infection may pass back from man to cattle (Magnusson, 1941, 1942, Griffith and Munro, 1944, Plum, 1940, Nielsen and Plum, 1939, Tice, 1944), and also from man to man, as in the five proved cases reported by Griffith and Munro (1935), Munro (1939), Jensen *et al* (1940), and Hedvall (1942).

The human type of tubercle bacillus may also infect cattle, as it has been observed that cows in contact with a human case of pulmonary tuberculosis, though developing no sign of active disease, may give positive tuberculin reactions. Many of these cases have been proved by the isolation of a human type of bacillus from the tissues of cattle which may show no active disease or minimal lesions in either the respiratory or the alimentary system (Giltner, 1923, Hindersson, 1933, Stenius, 1933, Bang and Jepsen, 1936, Crawford, M (personal communication), 1936, Plum, 1937, Van der Schaaf and Van Zweiten, 1939, Reid, 1939, Plum, 1940, Nielson and Plum, 1939, Feldman and Moses, 1941, Hillemark, 1942, Rosa, 1942, Magnusson, 1942). Neither Hindersson (1933) nor Plum (1936, 1937) succeeded in isolating human tubercle bacilli from the milk of cows naturally or experimentally infected with the human type. Thus infection of cattle with the human type is more of a nuisance, as it results in confusion at tuberculin-testing. Bovine infection, on the other hand, usually gives rise to serious losses. Someone in contact with a previously clean herd should be suspected when many positive reactors suddenly appear at routine tuberculin-testing.

The cycle of infection in man and in animals is thus much more complicated than originally suspected.

A Infection with the Human Type of Bacillus

1 Respiratory

The chief pathway of infection for tuberculosis in the human subject is via the respiratory system. In a consecutive post-mortem series of 434 cases of tuberculosis in children under 13 years the primary site of infection was found in the respiratory system in 283 (65.2%), in the abdomen in 140 (32.3%), and in the cervical glands in 9 (2.07%). No definite primary portal of infection could be identified in 7. (In 5 of the cases there appeared to be double sites of entry—one in the thorax and the other in the abdomen.)

Respiratory tuberculosis is most commonly caused by the inhalation of infected droplets, occasionally, however, pulmonary tuberculosis may be secondary to tuberculosis elsewhere, as, for example, in the mesenteric or cervical glands, due usually to blood spread from these sites. Tubercle bacilli must, however, be frequently inhaled without producing any recognizable lesion, and it must be assumed that in these cases the tubercle bacilli are destroyed by the resistance of the tissues of the healthy individual. It is thus not the bacillus itself, the presence of which is essential, but the harmonious working together of many factors which results in disease. These factors probably play a more important part in the pathogenesis of the disease than the organism, but the true nature of many of them and their mode of action is still obscure. Tuberculosis is a universal disease and the chances of infection are enormous, and it is a native or acquired resistance, or both which prevents the disease assuming epidemic proportions. Is this resistance humoral or cellular? It would appear to be more associated with the latter, as Lurie (1942) has shown experimentally that tubercle bacilli phagocytosed by the mononuclear leucocytes of normal animals are not killed whereas the same cells in actively tuberculous or immunized animals have increased bacteriostatic or bactericidal properties which seem to be independent of the body fluids as these properties remain after the cells have been transferred into a normal animal.

In a series of cases of primary respiratory tuberculosis in children under 13 years we isolated the human type of bacillus from the primary lung lesion or the tracheo-bronchial glands in 160 (96.4%) and the bovine in 1

TABLE I—Primary Respiratory Tuberculosis Types of Tubercle Bacilli

Type	0-1 year	1-2 years	2-3 years	3-6 years	6-13 years	Total
Human	58	31	21	24	26	160 (96.4%)
Bovine	1	2	2	1	—	6 (3.6%)

(Table I) Griffith and Munro (1944) in figures collected from various authors found that the types of tubercle bacilli occurring in the sputum of Scottish patients with pulmonary tuberculosis comprised 2,609 (94.3%) human and 160 bovine strains, and from cases in England, Wales and Eire 4,113 (98.1%) human and 81 bovine.

In most cases of human infection in childhood the source of infection is usually a near relative, and in a recent series of cases of meningitis of all ages due to the human type of bacillus investigated in Scotland the mother was the most frequent source (Table II). The significance of this family

TABLE II—Relationship of Contact to 144 Cases of Meningitis Infected with Human Strains

Father	22	Aunt	12	Grandfather	1
Sister	21	Uncle	6	Others	11

infection is important, as it subjects those coming in contact with it to repeated infections, and also to the liability of massive doses of tubercle bacilli. Both these factors may overcome any natural or acquired resistance possessed by a member of a family, more particularly should the resistance be lowered by acute disease, overwork, or malnutrition.

In childhood the primary infection results in the primary lung lesion, originally described by Parrot (1876) though often credited to Ghon (1916). It may also occur in adults and during the war period we observed typical childhood acute primary pulmonary lesions more often in the adult than formerly, due, I think, to the greater number of rural dwellers coming to work in factories in urban areas. The primary lung lesion in the child is usually small and m

be readily missed unless carefully searched for at necropsy (Blacklock, 1932). It is usually single, but why this should be so in view of the probability of multiple infections—as, for example, in the case of a child with a tuberculous parent—is unknown. The secondary lesion in the tracheo-bronchial glands in the child under 3 years is usually massive. The reason for the greater size of the lesion in the glands as compared with that in the lungs would appear to depend on the degree of hypersensitivity which the child has developed in the interval elapsing between the occurrence of the lesion in the lung and that in the glands. Owing to this hypersensitivity the lesion in the glands is more of an exudative type, and thus massive caseation occurs. In the older child the degree of tuberculosis in the tracheo-bronchial glands is usually less than that in the younger, in fact in older children and adults the glandular lesion may be entirely absent. Terplan (1946) has also noted this. In post-mortem examinations in adults small healed primary lung lesions are often found, and in a series of cases still being studied in the Royal Infirmary, Glasgow, only about 5% show any evidence of tuberculosis in the tracheo-bronchial glands. This relative absence of secondary lesions in the glands of older children may be partly accounted for by the more frequent evidence of healing as judged by the growth of fibrous tissue around the primary lung lesion. This fibrosis increases *pari passu* with age (Table III), and will close lymphatic channels

TABLE III—Primary Lung Foci in Children Evidence of Healing

Age	No. of Foci	Percentage Healing
6 months	40	0
12	58	10.3
2 years	62	37.1
3	40	40.0
6	44	52.2
13	46	67.4

and thus prevent the spread of the bacilli to the glands. This, however, is not the primary reason, for it is obvious that in order to allow granulation tissue to form and subsequent fibrosis to occur the bacilli must be fixed at the site of infection and prevented from undue multiplication, at least for a time, by some bodily defensive mechanism. Age is undoubtedly an important factor in determining healing. The longer the primary infection in the child is delayed the greater chance of resolution, particularly in the period between 5 and puberty, but why this should be so is unknown. This probably accounts for the higher mortality in children of the hospital class as compared with those who are better off. In the former there are more opportunities of infection occurring in early life, due largely to the overcrowded conditions under which most of them live, than in the latter, in whom primary infection is usually delayed until school age or later. A further and important factor is that between 5 and 14 years there is greater proportion of changes from a positive to a negative tuberculin reaction than at any other age (Zacks and Cartwell, 1942).

If the disease is not localized at or near the site of infection then, in the child, generalization occurs, resulting in acute generalized miliary tuberculosis with or without meningitis. The total human percentage for the latter in Scotland was 82.8 as reported by various workers between 1907 and 1947 (Watt, 1907; Wang, 1916–17; Blacklock, 1932; Griffith, 1934; Blacklock and Griffin, 1935; Macgregor *et al.*, 1935; Macgregor and Green, 1937; Macgregor and Scott, 1936; National Investigation (Scotland), 1933–4). The proportion of human infections was higher in the older than in the younger age groups (Table IV). The main portal of entry of human strains is via the lungs,

TABLE IV—Types of Tubercle Bacilli Cerebral Tuberculosis Scotland

Date	0–5 years		6–15 years		Over 15 years		Total

* Includes 2 cases ages not stated

and thus most of these cerebral deaths should be included with tuberculosis of the respiratory system, though by the Registrar-General they are tabulated separately under the heading of 'meningeal tuberculosis'.

The first infection in the lungs with tubercle is pathologically distinct from all others in that it affects a virgin soil and at its onset is localized. In most cases, particularly in older children and in adults, this localization persists and complete healing results. But the patient has now developed hypersensitivity, the degree of which varies from patient to patient for some years after the initial infection, though it tends to lessen as age advances. For example, in a series of still unpublished Mantoux tests which Griffin and I made in 1932–4 in 1,732 clinically non-tuberculous children, all under 13 years, testing each child first with 0.1 mg and thereafter, if negative, with 1 mg and 10 mg of old tuberculin, we found that of those who did not react to 0.1 mg the percentage who gave positive reactions with 1 mg increased as age advanced. The same was true of those who reacted negatively to 1 mg but positively to 10 mg (Fig. 2). On

account of this waning hypersensitivity in the older as compared with the younger child there is more of a formative response on the part of the fixed tissues, with resulting localization of the infection. The tissue reaction to reinfection tuberculosis, which in the adult is usually exogenous, depends on many factors such as degree of hypersensitivity and of immunity, dose and virulence of the infecting bacilli. Of these various factors hypersensitivity is the most easily investigated in the human subject, the others are difficult. Experimentally infected animals in which hypersensitivity has waned have acquired a high degree of resistance to any subsequent infection (Willis, 1928). The same would appear to be the case in the human subject, for in most adults healed primary lesions, often minute, are found post mortem. It should be noted however, that this acquired resistance is by no means absolute and may be broken down by acute and chronic disease, overwork, and malnutrition. A high degree of hypersensitivity is an unfavourable factor as demonstrated in animals by Rich and McCordock (1929) and in tissue cultures by Rich and Lewis (1928). These authors have shown that tubercle bacilli *per se* cause little necrosis in normal tissue, though they quickly do so when hypersensitivity is present.

FIG. 2—Results of a series of Mantoux tests showing increased percentage of reactions as age advances

2 Alimentary Infections

Figures for primary abdominal tuberculosis are small. The collected figures from 1914 to 1944 for Scotland (Mitchell, 1914b; Wang, 1916-17; Blacklock, 1932; National Investigation, 1943-4) show a total percentage of human infections of 22.1 (Table V). As most of the abdom-

* 2 human and 6 bovine cases included; ages not stated but under 12 years.

inal cases were examined post-mortem, care was taken to exclude any source of infection in the lungs from which the abdomen could have been infected. To account for these primary alimentary lesions human tubercle bacilli must have been swallowed in food contaminated by droplet infection or, in the case of young children, by fingers contaminated from floors on which droplets of sputum may have been present. In the case of children between 9 months and 2½ years Dieudonne (1901) recovered tubercle bacilli from the dirt on their hands in 2 of 15 cases. Still another method is through the imperfect cleansing of eating utensils, as has been demonstrated by Hutchinson (1947) for dysentery bacilli, streptococci, and staphylococci.

Of the cases of primary tuberculosis of the cervical glands investigated up to 1944 in Scotland (Mitchell, 1914a, 1914b; Griffith, 1915, 1929; Wang, 1916-17; Blacklock, 1932; Griffith and Smith, 1935; National Investigation, 1943-4) the proportion of infections with the human type was 27.8%. The human type of bacillus is thus not mainly responsible for tuberculosis of the abdomen and cervical glands.

B Infection with the Bovine Type of Bacillus

1 Alimentary

Infection with the bovine type of bacillus is mainly through the alimentary system, and accounts for the greater proportion of cases of cervical gland and abdominal tuberculosis in the various Scottish investigations (Table V). The highest proportion of bovine infections is found in early life, and this is probably due to the greater consumption of milk at that age than at any other. There are thus greater opportunities for infection should the milk contain tubercle bacilli. As the mucosa of the intestine and of the nasopharynx is a less favourable site than the lungs for attack by tubercle bacilli, which grow slowly, some coincidental lesion may probably allow the bacilli to invade these mucosae. The more frequent occurrence of acute catarrhal conditions in these sites in childhood as compared with adults may provide a *locus minoris resistentiae* in which tubercle bacilli may gain a foothold. This may partly account for the greater frequency of tuberculosis of the cervical glands and of the abdomen in children than in adults. Further, the possibility of acquired resistance due to an arrested infection in the lungs may also determine the relative infrequency of

alimentary tuberculosis in the adult as compared with a child. This is well exemplified in the case of a phthisic cavity in the adult where, in spite of a sputum containing numerous tubercle bacilli, secondary tuberculous ulcers may not be found in the intestine.

The rural inhabitant is more liable to bovine infection than the urban, as is shown by the greater incidence of bovine infections in cervical adenitis in country (77.8%) than in urban patients (46.2%) (Table VI). The fig-

TABLE VI—Permanent Residence of Patients, 1943-4 Investigation, Scotland

* In 1 case residence not stated.

for abdominal tuberculosis are too small to be used for comparative purposes, those for cerebral tuberculosis, however, show a bovine percentage three times higher rural than in urban cases. More detailed analysis of figures obtained in the 1943-4 investigation further confirms this higher proportion of bovine infections in rural areas. In tuberculous meningitis 8% were infected with bovine strains in the large burghs and cities of Scotland as against 15.9% in the rural areas of the counties; surgical tuberculosis 20.1% of the cases in the burghs and cities were caused by bovine infection, in the rural areas this percentage was more than double—45.4%. Bovine infection is thus more of a rural than an urban problem. This finding is further substantiated by figures for the western area of Scotland. In this area 56.7% of the entire population of the country reside, and Glasgow accounting for 39.8% of the population of the area. In 1914 there were in this area 3,219 (77.5%) of the 4,146 attested herds in Scotland. In Ayrshire, for example, 88% of the dairy herds are attested. This large proportion of attested herds in the western area partly accounts for the region having the lowest bovine percentage of all in Scotland in the meningitis series and the second lowest in the surgical series (Table VII). It is not the w-

TABLE VII—Percentage Bovine Infections, Cerebral and Surgical, Scotland

Area	Cerebral	Surgical
Eastern	27.3	54.2
North-eastern	26.7	44.1
South-eastern	13.4	43.7
Northern	8.3	24.0
Western	6.1	27.8

explanation, which is more apparent when the figures for the western area are analysed. In the meningitis cases Glasgow had a bovine percentage of 2.3, the large burghs in the Clyde Valley area had together 8.2, and the rural areas in the Western Counties 10.9. The corresponding bovine percentages in the surgical cases for these places were 8.8, 13.6, and 44.4, respectively. In Glasgow 95% of the milk sold for consumption is subjected to some form of heat treatment (45.9% pasteurized under licence, 49.1% heat treated, and 5% sold as raw milk), and this accounts in part for the very low bovine percentage in the city. In the large burghs the proportion of milk subject to some form of heat treatment is lower than in Glasgow, while in the rural districts of the western area from where Glasgow draws its milk supply any form of heat treatment is practically non-existent. Thus in Glasgow, partly owing to the extensive heat treatment of milk, the mortality rate for bovine meningitis is less than one quarter and the

morbidity rate in surgical tuberculosis due to bovine infection is one-fifth of those in the rural areas of the Western counties from which it draws its milk supply. Ruys (1946) has made similar observations in Amsterdam, where during the war practically all the milk was pasteurized, and where there was a decrease in bovine tuberculosis in children, though no such decrease was observed in the surrounding rural areas.
